PREFACE

THIS book is intended for pupils preparing for the General Certificate of Education at Ordinary Level. It also covers some of the ground for the earlier stages at Advanced Level. It was written at the request, and with the active co-operation, of a number of teachers of Geography.

It describes how Man is conditioned by his environment and how he, in his turn, responds to this environment. Thus the emphasis is on the human side of Geography and the main object is to show the nature of the world as the physical home of Man. For should not Geography give 'a conception of the world and of its diverse environments and peoples, which should enable boys and girls to see social and political problems in a truer perspective, and give them sympathetic understanding of other peoples'?

The political and economic changes that have taken place in recent years, partly as the outcome of the Second World War, and the increasing requirements of Examining Bodies, have necessitated a thorough revision of the book. In this new edition the text has been revised and many of the maps and diagrams have been redrawn. The maps and diagrams are designed to bring out salient facts and are intended to supplement, but not to replace, the maps in a good atlas. They have been compiled from the latest available information. The comparative diagrams, based on recent three years' averages, show the chief products of the countries concerned or other relevant facts connected with them. Actual figures are not given. They vary from year to year, but a study of statistical tables shows that (except in abnormal circumstances) *relative* production remains much the same over a considerable period. Even when studied by themselves import and export diagrams shed light not merely on the resources of a country, but often on its climatic conditions, its physical relief, and its progress, or otherwise, towards industrialization. As such the diagrams may be used by pupils for short but stimulating exercises.

I should like to express my thanks to Mr. John Myers for reading the proofs of this edition, and for preparing the diagram to illustrate the Polar Front; and also to Mr. A. L. P. Norrington.

Sections of the proofs have been sent all over the world for scrutiny by experts on the spot, as well as to many readers in the British Isles. Among others, I am indebted to the following, who kindly read and revised the sections mentioned in brackets after their names: Mr. W. D. Johnston, Johannesburg (Africa); Mr. G. E. D. Lewis, Penang (Malaya and the East Indies); Dr. E. Innes, Department of Economics, University of Toronto (Canada); Mr. Joseph H. Burlingame, Department of Geography, Milton Academy, Mass. (United States); and Mons. C. M. E. Billecoco (France). I also received much help from the officials of the Information Departments in London of the High Commissioners for Canada, Australia, New Zealand, and South Africa; from those of the Department of Mines and Resources, Ottawa; and from my colleagues in the Department of Geology and Geography of the University of British Columbia.

Oxford,

July 1963

J. H. S.

ACKNOWLEDGEMENTS

THANKS are due to the following bodies for permission to publish certain questions from their papers set for the General Certificate of Education and the School Certificate Examinations:

The Oxford and Cambridge Schools Examination Board; The University of Cambridge Local Examinations Syndicate; The Oxford Local Examinations Delegacy; The University of London University Entrance and School Examinations Council; The Northern Universities Joint Matriculation Board; The College of Preceptors; and to the Controller of H.M. Stationery Office for the Secondary Education (Scotland) Leaving Certificate Examination.

PART I

GENERAL GEOGRAPHY

CHAPTER I

MATHEMATICAL GEOGRAPHY

The Solar System. The *Earth* is a member of the Solar System. It is one of eight major planets revolving round the Sun, the centre of this system. The planets radiate no light of their own, but shine with that reflected from the Sun. Chief among them are Mercury and Venus, which are nearer, and Mars, Jupiter, Saturn, Uranus, and Neptune, which are farther away from the Sun than the Earth.

The *Sun* has a diameter of 864,000 miles. Though 93,000,000 miles from the Earth, so great is its heat that its rays reach our planet with considerable warming power.

The *Stars*, unlike the planets, are self-luminous bodies. They

appear small because they are so far away: the nearest star, *Proxima Centauri*, is 200,000 times more distant than the Sun. The stars do not revolve round the Sun, but move in circular paths across the sky while maintaining their relative positions. With the exception of the Pole Star, which is practically overhead at the North Pole, the stars on any given night appear to be changing their positions, but these apparent movements are really due to the rotation of the Earth.

The *Moon* is a dead planet. It is about 240,000 miles from the Earth and, as it is thus some 370 times nearer to us than the Sun, it appears almost as big as the latter body. The Moon revolves round the Earth taking approximately twenty-nine days to complete its circuit. The *phases* of the Moon are the result of its position in relation to the Earth and the Sun (see Fig. 1). At new moon, when

FIG. 1.

the Moon is between the Earth and the Sun, all three bodies are practically in a straight line. At full moon they are again almost in a straight line, but now the Moon is on the opposite side of the Earth from the Sun. When the Moon is in its first and third quarters its direction from the Earth is at right angles to that of the Sun. The Moon's orbit is elliptical and inclined at an angle of 5° to the plane of the Earth's orbit. This explains why we do not have a total *eclipse* of the Sun every time there is a new moon.

The Shape of the Earth. At one time men thought the Earth was flat but now we know it is a globe. Magellan deserves the title of the 'first circumnavigator'; for though he himself died in the Philippines, the crew of his ship, the *Victoria*, arrived in Spain in 1522, having sailed round the world during their three years' voyage. When a ship goes out to sea, as it draws farther and farther from the land, first the hull and then the funnels appeared to sink gradually into the water just as if the vessel were steaming downhill. Now seamen tell us that the same thing occurs all over the world: a ship in the far distance appears to be either sinking or rising according as it is sailing from or to the observer. It is therefore concluded that the surface of the Earth is curved, and curved equally, like the circumference of a ball. This conclusion is confirmed by the careful measurements and calculations of men of science. And it is also certain that the Earth is a globe, or sphere—not a perfect sphere, but one very slightly flattened at the top and bottom. The equatorial diameter is 7,926 miles and the polar diameter 7,900 miles.

There are many other proofs that the Earth is a globe. Here is one. When there is an eclipse of the Moon the shadow cast by the Earth on its surface is always curved.

The Size of the Earth. About 2,000 years ago, Eratosthenes, a Greek living in Egypt, calculated the size of the Earth. On Midsummer Day, at noon, he found that the Sun at Aswan was in the *zenith*, that is at a point in the heavens directly overhead. He also found that at the same time, on the same day, the Sun at Alexandria was 7° from the vertical. He knew that the distance from Aswan to Alexandria was 5,000 stadia (10 stadia = 1 English mile), and that the circumference of the Earth was divided into 360 degrees. Thus, by a single calculation, he obtained his result.

In Fig. 2 *B* is Aswan, with the Sun directly overhead at the zenith (*S*). The line drawn from *S* to *B* goes straight to the centre of the Earth (*C*). *A* is Alexandria, *T* the zenith of Alexandria, *RA* the line of the Sun's rays. $\angle TAR$ (7°), showing the distance of the Sun's rays from the vertical, is equal to $\angle ACB$ at the Earth's centre, which is therefore equal to 7° .

If 7° are represented by 5,000 stadia,

then 360° are represented by $(5,000 \times 360) \div 7 = 1,800,000 \div 7 = 257,000$ stadia, or 25,700 English miles.

This was a remarkable result when we remember that the measuring instruments used by Eratosthenes were not nearly so accurate as those of to-day. The circumference of the Earth is 24,902 miles, or approximately 25,000 miles.

The Rotation of the Earth. Though the Earth appears to us stationary, it is, in fact, spinning round on its axis. The axis is, of course, an imaginary line the ends of which we call the North and South Poles. The Earth rotates on its axis once in every 24 hours. It spins from *west* to *east* and, as it rotates, any particular part gradually passes under, and then turns away from the Sun, until at last the latter is no longer visible. Thus the Earth's movement on its axis gives us the phenomena of day and night: any spot on the surface has day when it faces the Sun, and night when it is turned away from it.

FIG. 2.

The Revolution of the Earth. Besides spinning on its axis, the Earth, as we know, changes its position in the firmament, and moves round the Sun. The path of the Earth round the Sun, called its *orbit*, is not a circle, but an oval or ellipse; and the plane in which the Earth moves is said to be the *Plane of the Ecliptic*. The time taken to complete one revolution round the Sun is one year, or approximately $365\frac{1}{4}$ days. For convenience sake, one year

is taken as 365 days, except during a Leap Year when one day is added.¹

The Earth's axis is inclined to the plane of its orbit at an angle of $66\frac{1}{2}^{\circ}$.

As the axis always points in the same direction, therefore the northern half of the Earth (the Northern Hemisphere) is tilted towards the Sun for half the year, and the Southern Hemisphere during the other half of the year. When the Northern Hemisphere

FIG. 3.

is tilted towards the Sun, the North Pole has continuous daylight, but the South Pole is in darkness (see Fig. 3). When the Southern Hemisphere is tilted towards the Sun these conditions are reversed (see Fig. 4). *The seasons are due to the changes of the Earth's position in the course of its revolution about the Sun, and to the inclination of its axis (see Fig. 6).*

The Path of the Sun. * The Equator is an imaginary line drawn round the Earth midway between the Poles. Certain imaginary lines north and south of the Equator are called *tropics*, the northern being the Tropic of Cancer ($23\frac{1}{2}^{\circ}$ N.), and the southern the Tropic of

¹ The actual time to complete one revolution round the Sun is 365 days 5 hours 48 minutes 46 seconds. Leap year occurs every fourth year except at centuries. A century is a leap year when the first two figures are divisible by 4.

Capricorn ($23\frac{1}{2}^{\circ}$ S.) (see Fig. 5). The word tropic means 'turning place'. At one time men imagined that the Sun turned south on

FIG. 4.

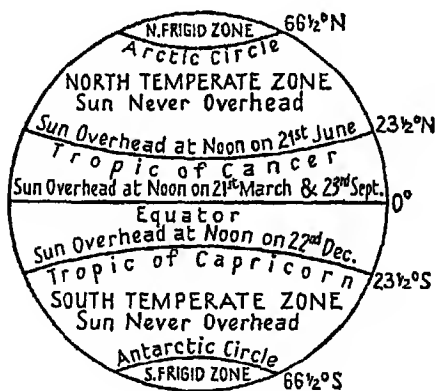

FIG. 5.

June 21st and north on December 22nd. ^{*} Because the Sun stops its apparent northward movement on June 21st this date is known as the *Summer Solstice* (from a Latin word *solstitium*, meaning the

standing still of the Sun); while for a similar reason December 22nd is called the *Winter Solstice*.

The inclination of the Earth's axis, together with its revolution round the Sun, is the cause of the varying length of day and night in different parts of the world. At the Vernal Equinox (*aequus* = equal; *nox* = night), March 21st, and the Autumnal Equinox, September 23rd, the Sun is overhead at the Equator (Fig. 6). On

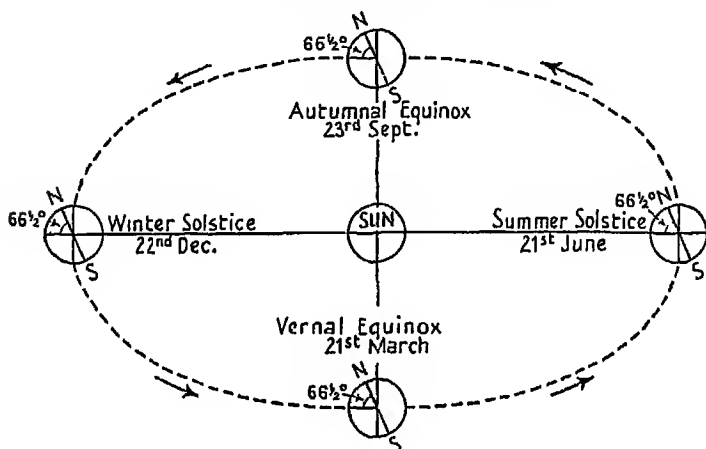

FIG. 6.

these dates, except at the Poles, (a) days and nights are equal all over the world; and (b) the Sun rises exactly due east and sets exactly due west at all places on the Earth's surface.

At the Equator itself days and nights are equal throughout the year. The Sun rises about 6 a.m. and sets about 6 p.m. There is no twilight. It is almost as if a drop curtain were suddenly let down over the Sun. Throughout the tropics very similar conditions prevail: the length of the days varies little and it gets dark rapidly about 6 p.m.

Between March 21st and September 23rd, when the North Pole is tilted towards the Sun, the days are longer than the nights throughout the Northern Hemisphere. From March 21st till June 21st (when the Sun is overhead at the Tropic of Cancer) the length of the day increases from the Equator towards the North Pole. Each day

the Sun (*a*) rises a little earlier, and a little more towards the north of east; (*b*) reaches a greater height at midday; and (*c*) sets a little later, and slightly more towards the north of west. From June 21st until September 23rd the changes are in the opposite direction, but the days are still longer than the nights. On September 23rd the Sun's path is similar to that on March 21st.

Between September 23rd and March 21st, when the Southern Hemisphere is tilted towards the Sun, conditions are reversed. In the Southern Hemisphere the days are longer than the nights, while in the Northern Hemisphere the nights are now longer than the days.

At the North Pole there is continuous daylight from March 21st to September 23rd. The Sun does not rise or set, but circles round and round in the sky. On March 21st it circles round just on the horizon, and each day it circles somewhat higher until June 21st when it moves round at a height of $23\frac{1}{2}^{\circ}$ above the horizon. Then gradually its path becomes lower until, on September 23rd, it again circles round just on the horizon, after which it disappears for six months. There are some weeks' twilight before March 21st and after September 23rd. The length of the day decreases from six months at the North Pole towards the Arctic Circle ($66\frac{1}{2}^{\circ}$ N.) where there is only continuous daylight for 24 hours on June 21st.

Similar conditions are experienced in the corresponding Antarctic region from September 23rd to March 21st.

Latitude and Longitude. The position of a place on the Earth's surface can be fixed when we know its latitude and longitude.

Latitude is distance, measured in degrees, north or south of the Equator.

The circumference of the Earth (25,000 miles), being a circle, is divided into 360 degrees. Therefore $1^{\circ} = 25,000 \div 360 = 69\frac{1}{2}$, or approximately 70 miles. This figure is useful in determining the scale of a map.

One of the easiest ways of finding the latitude of a place north of the Equator is to find the *altitude* (the angular distance above the horizon) of the Pole Star, which is the *zenith* of the North Pole, or the point in the heavens directly above the North Pole. Take a telescope and look at the Pole Star through it. The angle made by the telescope with a horizontal line, found by means of a spirit level, will give the altitude of the Pole Star. This altitude is equal to the latitude of the place. As the star is overhead at the North Pole, the

angle through which the telescope would move there would be 90° , which is the latitude of the North Pole. At the Equator the Pole Star is on the horizon, and therefore the angle is 0° , which is the latitude of the Equator.

Mariners and airmen use a *sextant* to determine latitude. By means of this instrument the altitude of the Sun, or of other heavenly bodies, can be measured. Each day at noon ships' officers, by

FIG. 7a.

by means of the sextant, find the altitude of the Sun. After this has been ascertained the exact latitude of the vessel is worked out by reference to the Nautical Almanac, which gives the *Declination of the Sun* (that is, its distance north or south of the Equator) for every day in the year. From 21 March to 23 September the Sun has a *north declination*; and from 23 September to 21 March it has a *south declination*. When determining

the latitude of a place in the Northern Hemisphere the north declination must be added to the Sun's zenith distance, whereas the south declination must be subtracted from it. The Sun's *zenith distance* is its distance from the vertical.

Relation of the Latitude of a place to the Sun's altitude.

At the Equinoxes (21 March and 23 September) the Sun is overhead at noon at the Equator. In Fig. 7a the Sun's *zenith distance* is represented by $\angle ZAT$. This angle, which is obtained by subtracting the Sun's altitude, $\angle TAY$, from 90° , is seen to be equal to $\angle AOE$, which is the latitude of A.

\therefore at the Equinoxes, $\text{Latitude} = 90^\circ - \text{the Sun's altitude}$.

In the Northern Hemisphere on 21 June (see Fig. 7b), the Sun is $23\frac{1}{2}^\circ$ higher in the sky than on 21 March. Therefore it has a north declination of $23\frac{1}{2}^\circ$. The Sun's zenith distance (represented by $\angle ZAT$) is equal to $\angle AOD$ to which $23\frac{1}{2}^\circ$ (i.e. the Sun's north declination) must be added to make it equal to $\angle AOE$, the latitude of A.

\therefore on 21 June, $\text{Latitude} = 90^\circ - \text{the Sun's altitude} + 23\frac{1}{2}^\circ$.

In the Northern Hemisphere on 21 December (see Fig. 7c) the Sun is $23\frac{1}{2}^\circ$ lower in the sky than on 23 September. The Sun's *zenith distance*, $\angle ZAT$, is equal to $\angle AOD$, from which $23\frac{1}{2}^\circ$ (the Sun's *south declination*) must be subtracted to make it equal to $\angle AOE$, the latitude of *A*.

\therefore on 21 December, $\text{Latitude} = 90^\circ - \text{the Sun's altitude} - 23\frac{1}{2}^\circ$.

FIG. 7b.

FIG. 7c.

How to find the latitude of a place in the Northern Hemisphere on any given date by means of the Sun's altitude at noon.

Suppose the date to be 1 January.

The Sun's altitude is found to be 12° and the Sun's declination is 23° S.

$$\begin{aligned}\text{Then the Latitude} &= 90^\circ - \text{Sun's altitude} - \text{Sun's declination.} \\ &= 90^\circ - 12^\circ - 23^\circ \\ &= 90^\circ - 35^\circ \\ &= 55^\circ \text{ N.}\end{aligned}$$

Suppose the date to be 1 June.

The Sun's altitude is found to be $60\frac{1}{2}^\circ$ and the Sun's declination is 22° N.

$$\begin{aligned}\text{Then the Latitude} &= 90^\circ - \text{Sun's altitude} + 22^\circ \\ &= 90^\circ - 60\frac{1}{2}^\circ + 22^\circ \\ &= 112^\circ - 60\frac{1}{2}^\circ \\ &= 51\frac{1}{2}^\circ \text{ N.}\end{aligned}$$

In the Southern Hemisphere the latitude of a place is found in a similar way, except that a north declination is subtracted from, and a south declination is added to the Sun's zenith distance.

Determination of Longitude. Just as in finding latitude we measured from a fixed line, the Equator, so too we must have a fixed line, running due north and south, for measuring longitude. Such a line is called a meridian. *Longitude is distance, measured in degrees, east or west of any fixed meridian.*

FIG. 8.

The Equator is divided into 360 degrees, and on the map, or the globe, lines are drawn through some of these points, at regular intervals, to the Poles. These meridians are all equal circles which cut each other at the Poles. The meridian passing through Greenwich is usually taken as the one from which measurements are calculated. This meridian is numbered 0°. On a globe the meridians are numbered from 0° to 180° west or east. At the Equator the degrees are approximately 69 miles apart. But obviously the space between any two diminishes as they approach each other towards the Poles, where they cut. Therefore lines of longitude cannot be used to estimate the scale of a map.

As the Earth takes 24 hours to make a complete turn on its axis, the 360 meridians of longitude take 24 hours to pass under the Sun.

Therefore 15 degrees pass under the Sun each hour, and 1 degree in 4 minutes. *It is noon at a place when the meridian of longitude of that place passes directly under the Sun.* Thus all places on the same meridian have their noon at the same time. As the Earth spins from west to east, places east of the meridian 0° pass under the Sun before places west of this meridian. When it is noon at Greenwich, at a place 1° E. it is 4 minutes past noon; i.e. 12.4 p.m.; while at a

FIG. 9. Time-belts of North America.

place 1° W. it is 4 minutes before noon, i.e. 11.56 a.m. Fig. 8 shows part of the Northern Hemisphere as we should see it, at the equinoxes, looking down on it from a point above the North Pole. As the Earth rotates from west to east, dawn is just breaking at Greenwich and the Sun is on the horizon.

When sailors wish to find their longitude, then the time when the Sun crosses the meridian (i.e. when the Sun is at its highest) is noted. Suppose this time is 3 p.m., as shown by the ship's chronometer which registers Greenwich time. This means that local noon is 3 hours *after* Greenwich noon. Therefore the longitude is *west*. The Earth has turned on its axis, since Greenwich noon, through an angle of $3 \times 15 = 45^\circ$. The longitude of the vessel is, therefore, 45° W. Nowadays, though Greenwich Mean Time (G.M.T.) can be obtained by wireless, ships still carry chronometers. In actual practice, however, the calculation is not quite so simple.

Standard Time. All places in the same area use what is called standard time. Thus clocks in the British Isles are set to Greenwich standard time, for it would be very inconvenient if they followed local time. If, for example, clocks at Fishguard (5° W.) were set by local time, a man travelling from London to Fishguard would find that his watch, showing Greenwich time, was 20 minutes fast when he arrived. Western Europe uses Greenwich time, but Central Europe takes its time from the local time along the meridian 15° E., and Eastern Europe from the meridian 30° E. In Canada there are five time-belts (Fig. 9). In the Atlantic belt the time is taken from the meridian 60° W. In this belt the clocks are 4 hours slow by Greenwich time. The other time-belts of Canada are Eastern (75° W.), Central (90° W.), Mountain (105° W.), and Pacific (120° W.). There are only four time-belts in the United States.

The International Date Line. If we travelled westward to a place X, almost on longitude 180° W., we should find the time there was nearly 12 hours behind Greenwich time. If we journeyed eastward to a place Y, almost on longitude 180° E., the time there would be about 12 hours ahead of Greenwich time. Suppose, for example, it is 8 a.m. at Greenwich, on Monday July 16th. Then at X, nearly on longitude 180° W., it is almost 8 p.m. on Sunday, July 15th, but at Y, almost on longitude 180° E., it is nearly 8 p.m. on Monday, July 16th. Thus X and Y, both almost on 180° , have approximately the same time, but differ in date by a day. Similarly ships travelling westward round the world (i.e. through 360°) lose a day, while those going eastward gain a day. To overcome the confusion that would otherwise arise, the *International Date Line* has been established. It runs along 180° E. or W. (for these meridians are, of course, the same) and westward-bound vessels crossing it drop a day from the calendar, while those going eastward add a day, by giving the same date to two consecutive days. The meridian 180° was chosen because it passes through the mid-Pacific where, owing to the small amount of land, the change of date causes the least inconvenience. Actually, the line deviates in places from 180° so as to avoid cutting through groups of islands, like the Fiji Islands, where it swings east to include the whole group.

Great and Small Circles. On a flat surface the straight line joining any two points is the shortest distance between them, but on a

globe all lines are curved. Such curves, when produced in either direction, form circles. If we cut a globe right through its centre, it will be divided into two equal portions, and the mark made by the cutting line will be the largest possible circle that can be drawn upon the surface. Such a circle is called a *Great Circle*. All great circles on the globe are the same size. Lesser circles, called *Small Circles*, whose planes do not pass through the centre of the globe, can also be drawn upon its surface. The *Equator* is that great circle, drawn midway between the Poles, which divides the Earth into two equal parts called Hemispheres. All other parallels of latitude are small circles. If we examine a globe we shall see, however, that all meridians of longitude are half great circles. *The shortest distance between any two places is the route following the arc of the great circle passing through them.* Steamers, where possible, follow the arc of a great circle, that is of a circle of which the centre of the Earth is the centre. Similarly, aircraft flying across oceans, such as the Atlantic and Pacific, follow great circle routes. Compare the relative positions of Moscow and San Francisco on a map and on a globe. The globe shows that the most direct way to fly between these two places is by the great circle route, passing through the polar regions.

The Magnetic North. Helmsmen steer by a mariner's compass. This is a very delicate instrument, but in essentials it consists of a magnetized needle, mounted horizontally on a pivot which allows it to swing freely. When the needle comes to rest one end points to the North Magnetic Pole and the other to the South Magnetic Pole. But these poles do not correspond exactly with the geographical poles. Neither is their position constant. In 1937 the position of the Magnetic North Pole, according to Admiralty charts, was latitude $70^{\circ} 40' \text{ N.}$, longitude $95^{\circ} 5' \text{ W.}$ The angle between the magnetic north and the geographical north is called the *magnetic variation*, and in calculating the true (geographical) north allowance must be made for this difference. This variation is shown on ordnance maps, and on charts used for sea and air navigation. In England the average annual change in the variation is $10' \text{ E.}$ At Oxford in 1911, the compass pointed to a direction $16^{\circ} 40'$ to the west of north; and, therefore, there was a magnetic variation of $16^{\circ} 40' \text{ W.}$; in 1931, the magnetic variation at Oxford was $13^{\circ} 20' \text{ W.}$, but in 1951 it was only 10° W.

In Arctic and Antarctic regions the influence of the Magnetic Poles affects compasses considerably, causing them to lose directional force. To offset this, mariners, airmen, and explorers in these regions use compasses fitted with dip needles, which have an up-and-down as well as a roundabout action.

EXERCISES

1. Give three reasons for supposing that the Earth is a ball.
2. Why is it that at the Equator the duration of daylight is almost constant throughout the year, while in the Arctic Circle it varies from 24 hours to zero?
3. State how daylight varies in Britain (*a*) with the summer and winter seasons, (*b*) with latitude in summer. In each case draw fully labelled diagrams to show the causes of the facts you state.
4. Define (*a*) *latitude* and (*b*) *longitude*. Why are degrees of latitude of equal length and degrees of longitude of unequal length, as measured on the Earth's surface? What is meant by local time? Given that Africa measures 2,400 miles along the Equator, what time is it on the east coast when it is noon on the west coast?
5. What do you mean by: the Zenith Distance of the Sun; the Declination of the Sun; the International Date Line; Magnetic Variation; Great Circle Sailing?
6. (*a*) When it is noon at Greenwich, what is the time at Leningrad (30° E.), New Orleans (90° W.), Melbourne (145° E.), and Calcutta (88° E.)? (*b*) Memphis (U.S.A.) is exactly north of New Orleans. What is the distance between these towns, the latitudes of which are 35° N. and 30° N. respectively? (*c*) On a map of Canada the distance between parallels of latitude 50° N. and 60° N. is 1.75 inches. What is the scale of the map?
7. (*a*) In what time-belts are (i) Montreal, and (ii) Vancouver situated? (*b*) What is the time at Vancouver when it is noon at Montreal? (*c*) When it is noon at Vancouver what is the time at Montreal? (*d*) At what time would the radio commentary on an ice-hockey match at Winnipeg, commencing at 8 p.m., be heard at (i) Minneapolis, (ii) Vancouver, (iii) Halifax, N.S.?

CHAPTER II

THE LITHOSPHERE

Materials of the Earth's Crust. The lithosphere, or outer crust of the earth, which is not more than ten miles thick, is made up of a great variety of rocks. The term *rock* is applied by geologists to all materials of which the earth's crust is composed, whether they be hard like granite and slate, or soft like sands, clays, muds, and chalk. These rocks affect the type of scenery, the fertility of the soil, the water supply, the kinds of buildings, and the occupations of the people. Rocks are made up of substances called *minerals*. Many of the minerals of which rocks are composed are the raw materials from which metals are obtained. When rocks contain compounds of metals in quantities sufficient to work commercially, such compounds are termed *ores*. Ores are often found in mountainous districts where folding or fracturing has brought ore-bearing rocks to the surface. Ores often occur in *veins*, or seams, that may vary from a few inches to many feet in thickness. Thus a seam may be compared to a sandwich between layers of 'country rock', as the ordinary rock found in a locality is termed.

The rock structure can be seen in railway and road cuttings, in quarries and other excavations, in mines, wells, and borings.

(1) Most *sedimentary* rocks were originally deposited in layers on the beds of lakes, seas, and rivers: they are easily quarried and worked. Such rocks include sand and sandstone; clay and shale; limestone and chalk, and others, known as carbonaceous rocks, such as lignite, coal, and anthracite. Since most of these rocks have been formed in seas and lakes, they often contain fossils—the hard remains of animals—which are especially abundant in limestones, chalk, and clays, and are frequently found in sandstones. Sedimentary rocks contain metals, and in some districts alluvial deposits of gold or tin are obtained by *placer mining* and similar methods. *Petroleum* is found in certain sedimentary rocks.

(2) *Igneous rocks* are those which have solidified from the molten condition.

(a) When such rocks are poured out on the surface, either through volcanoes or great fissures in the earth's crust, they cool rapidly, and

the resultant rocks, which are usually fine grained, are known as *volcanic*. Among the best-known examples is basalt. Sometimes very rapid cooling—as in the formation of obsidian and pitch-stone—gives the rocks a glassy appearance (rather like dark bottle glass).

(b) *Plutonic rocks* are formed when the molten material solidifies at considerable depths and consequently under great pressure. Rocks, like granite, which are formed in this manner are usually coarsely crystalline. When cooling takes place at a somewhat lesser depth the rocks, such as dolerite, are somewhat finer grained. Denudation, or earth movements, may bring plutonic rocks to the surface, when they often form infertile areas, such as Dartmoor.

Valuable minerals do not, as a rule, occur in igneous rocks, but they are often found in adjacent areas, where they were probably formed by the deposit of mineral matter, due to the cooling of hot solutions and gases, associated with the formation of such rocks. Fossils, coal, and petroleum are never found in igneous rocks.

(3) *Metamorphic*, i.e. *altered rocks*, are the result of long-continued pressure, heat, and other chemical or physical changes. Rocks like slate have been only slightly modified. But the original characters have been completely changed in some metamorphic rocks. As a rule metamorphic rocks, like gneiss and schist—two of the commonest—are hard and resist weathering. They form areas of rugged scenery and scanty infertile soils which, like Scandinavia, Finland, and the Canadian Shield, are thinly peopled. On the other hand, the presence of minerals in such areas may cause a concentration of people in scattered mining districts.

Soils. The upper layers of rocks weather to form the soil. Substances derived from rock waste include minerals, such as compounds of aluminium, phosphates, and potash. Iron compounds are mainly responsible for the brown and red colouring of soils, and their dark colouring is usually due to a high proportion of *humus*, or decayed vegetable matter. Leaf-mould and other vegetable matter is worked into the soil by earthworms, field mice, etc., and plant decay is further aided by bacteria. In the natural state plants decay where they grow and return to the soil all they have taken from it, including valuable products, such as nitrogen, also obtained from the air. On cultivated lands, where crops are carried away for

Man's use, the land must be kept in good heart by means of fertilizers—lime, nitrates, potash, phosphates, and so on.

If we visit a quarry we shall notice that between the underlying bedrock and the surface there are three distinct layers, or *horizons*. The uppermost layer forms the topsoil, or *A horizon*. Rain-water percolating through the topsoil washes down the finest particles of soil (clay) into the second layer, and also dissolves and washes

FIG. 10. A Soil Profile.

down soluble materials. This washing-down process is known as *leaching*. The second layer, called the subsoil, or *B horizon*, is fine and compact because of the materials washed down into it. The third layer, termed the *C horizon*, is made up of decomposing and much-broken rock, known as mantle-rock.

The type of soil depends on a number of factors, namely climatic conditions, the nature of the parent rock, relief, vegetation, and the period over which it has been worked by Man. The last factor is especially important in a small country like the British Isles, which has been intensively cultivated for centuries. But in a huge country, such as Russia, where conditions are uniform over enormous areas, the nature of the soil depends primarily on climate. Soils may be broadly classified as (a) Forest, (b) Grassland, and (c) Desert types.

(a) *Forest Soils.* (i) In the coniferous forests, with long cold winters and little evaporation, the soil is cool and damp. These

conditions do not favour bacteria and earthworms, etc., and the litter from the pine trees forms a mat on top of the ground. This becomes very acid, and the water seeping through it is so strongly acid that it leaches the brownish oxides of iron from the topsoil, leaving it an ashy-grey colour. Such infertile soils are described as *podsoils* (Russian: *pod* = under, *zola* = ash). (ii) The climate is more favourable in the deciduous forest belts, where, especially in Europe, large areas have been cleared for cultivation. Under the natural vegetation the leaf-mould is soon worked into the soil, and as this is only weakly acid, the iron oxides are not leached out of the topsoil, but remain to give it a brown colour. These soils are known as *brown forest soils*, or, under cultivation, as *brown earths*. (iii) In the tropical forest belt, with its high temperatures and heavy rains, dying plants decay too rapidly for much humus to form. Soluble materials are leached out of the top soil, but the red or yellow iron oxides remain, and give the soil a red or yellow colour. *Red and yellow forest soils* soon lose their fertility, but respond quickly to fertilizers.

(b) *Grassland Soils*, such as the Black Earth Lands of the Russian steppes, are black because they are rich in humus, derived from the decayed roots of grasses. Owing to the low rainfall, there is little leaching. Hence, the soluble salts tend to remain in the topsoil, providing abundant plant foods, which enable the *black earth soils* to retain their fertility for long periods. On the drier parts of the steppes, owing to the scantier grass covering, the soil is less rich in humus, and because of its chestnut-brown colour it is known as *brown-steppe soil*.

(c) *Desert Soils*. Lack of rain and scanty vegetation cause these soils to be poor in humus, but they contain much mineral matter. They are usually light and variable in colour. In the driest parts they are grey. Towards the grassland margins they are brown, and are fertile when irrigated, though in time salts tend to accumulate and render them useless for cultivation.

Soil Erosion. In many parts of the world the normal processes of denudation have been greatly accelerated by man, who by destroying the vegetation cover has caused the soil to be washed away by water, and blown away by wind. This man-made erosion has been going on for centuries. To-day, except for certain mountain areas, soil

erosion is most prevalent in semi-arid grassland regions, such as the steppes, the prairies, and the veld. In mountain areas soil erosion usually begins with the destruction of the forests. Once they are removed the rain, instead of sinking into the ground, washes the soil down the slopes, and *sheet erosion* commences, each succeeding rain-storm removing a thin layer of absorbent top soil. This initial stage is followed by *gully erosion*, when the run-off scours out tiny channels that grow deeper and wider until well-defined gullies are formed. Meanwhile, owing to the increasing run-off of silt-laden water, the rivers become subject to calamitous floods, such as those that do great damage in the Mississippi valley (see p. 391).

Equally disastrous is *wind erosion*. It is common in grassland areas, which suffer far more from wind than from water erosion. In parts of the High Western Plains of the United States, over-grazing and the attempt to cultivate unsuitable land have removed the vegetation covering, and the wind literally strips the unprotected soil from the land and carries it away in dust-storms (see p. 24).

Steps to combat soil erosion include (a) *terracing*, the traditional method of the Old World; (b) *contour ploughing*, i.e. ploughing along the contours instead of up and down the slopes; (c) *strip cropping*—planting along the slopes cover crops, such as grasses, which, by protecting the soil and absorbing moisture, allow more open crops to be planted alternately with them; (d) *planting shelter belts* of trees to break the force of the wind and retard soil movement; and (e) *plugging the gullies* by (i) building small dams, or (ii) fixing wire netting, or (iii) planting trees across them, all of which check flood water and so cause a deposit of silt.

The Relative Age of Rocks. Rocks are classified according to their *relative* age. The table (p. 513) is given for reference only.

EXERCISES

1. Describe how Sedimentary, Igneous, and Metamorphic rocks have been formed. Give examples of each type from the British Isles.
2. Where and why does soil erosion occur on a large scale? Describe some of the methods used to combat the problem.
3. To what factors are the characteristics of a soil chiefly due? What are the causes of the differing colours of soils, and what is the relation of these colours to the fertility of a soil?

CHAPTER III

THE CHANGING FACE OF NATURE

THE surface of the earth is undergoing constant change. Sometimes, as in the case of earthquakes and volcanic eruptions, such changes take place with dramatic suddenness, but usually they are so gradual as to be almost imperceptible. The mountains of to-day may become the plains of to-morrow, but so far as Nature is concerned both ' to-day ' and ' to-morrow ' cover a period of hundreds of thousands, or possibly of more than a million years. Great mountain-building movements result in the formation of mighty ranges ; but ice, running water, and other forces of denudation are continually wearing away the land.

TYPES OF MOUNTAINS

(1) **Fold Mountains** (see Fig. 11). In past geological ages disturbances in the Earth's interior have caused crumpling and cracking of the crust. But even now the Earth's crust is in a most unstable condition, especially in certain areas. The great upfolds (anticlines) form fold-mountains, and the downfolds (synclines) longitudinal valleys. Geologically speaking, such mountain systems as the Alps and the Rockies are young fold-mountains, whose scenery is rugged and majestic owing to the fact that as yet they have suffered relatively little denudation.

(2) **Residual Mountains** (Fig. 12). In the course of ages ancient mountains, like the Highlands of Scotland and Scandinavia, have become worn down by prolonged denudation, which has removed the softer rocks, leaving the harder and more resistant ones standing as peaks and plateaus. Mountain regions formed in this way are known as Residual Mountains, or Dissected Plateaus. Still further denudation results in the formation of peneplains (*pene* = almost), such as the Hudson Bay Lowlands.

(3) **Crust-block Mountains and Rift Valleys** (Fig. 13). We have already seen that in addition to forming upfolds the crust of the earth also cracks under the strain of accommodating itself to the decreasing size of the interior. Often where such cracks occur the portions on either side slip against each other ; one part rising up and the other slipping down. This slipping movement is known as

faulting. Cross Fell Edge, overlooking the Eden valley, was formed in this way.

Sometimes two parallel faults occur. The portion between them may (a) either be left standing above the surrounding country while

FIG. 11. Fold Mountains: an early stage, such as may be seen in the Juras.

FIG. 12. A late Stage in the Denudation of Fold Mountains.

Diagrammatic section of a crust-block

A rift valley bordered by crust-block mountains

FIG. 13.

the land on either side subsides, or (b) may be uplifted bodily above the adjacent country. Elevated mountain masses formed in this way are known as *Crust-block Mountains* or *horsts*. The Central Plateau of France and the Meseta of Spain are examples of this type.

In other cases the strata between two parallel faults subside to form a *Rift Valley*, which thus lies between two parallel sets of crust-block mountains. In this way was formed the Rhine Rift Valley between the Vosges and the Black Forest. The greatest rift valley in

the world is that stretching from the Jordan-Dead Sea trough, through the Red Sea to Lake Nyasa, in East Africa.

Somewhat similar to crust-block mountains are the great plateaus lying between fold-mountains. Many are of vast extent and lie at high altitudes. Among them may be mentioned the Plateau of Tibet between the fold ranges of the Himalayas and those of the Kunlun; and the Plateau of Bolivia, enclosed by ranges of the Andes.

FIG. 14. Section of a Volcano.

(4) **Volcanoes** (Fig. 14). A volcano is an opening in the earth's surface through which are erupted steam, gases, molten rock, dust, ashes, and other liquid and solid matter. The accumulation of material around the vent gives to the volcano its typical cone-like shape. The *neck*, through which materials are ejected, may be compared to the stem of a funnel leading to the bowl forming the *crater*.

Some volcanoes are built up almost entirely of cooled lava; others mainly of solidified ash, called *tuff*, and other fragmentary matter thrown out during an eruption. But the majority of cones consist of alternate layers of lava and tuff. Subsidiary cones are often formed at the sides of the volcano. Sometimes the crater becomes blocked up with solidified lava and ultimately the enormous pressure inside blows a portion of the mountain away. This happened in the case of Vesuvius, which is merely the remains of a much greater volcano, known as Somma, a large part of which was blown away in A.D. 79, when Pompeii was buried beneath clouds of volcanic ash and Herculaneum by a torrent of boiling mud.

Distribution of Volcanoes. Most of the world's volcanoes are found in regions of young fold-mountains whose crests especially have

been weakened as a result of earth-movements. Such volcanoes act as safety-valves for subterranean energy. Of the 415 active volcanoes in the world no fewer than 337 are found in the fold-mountains margining the Pacific, or on islands in that ocean. Among them may be mentioned those two majestic cones in the Hawaiian Islands, Mauna Loa and Mauna Kea, both of which rise about 14,000 feet above the surface of the ocean. An extension of the Pacific 'Ring of Fire' is found in the volcanoes of Java, Sumatra, and other islands in the East Indies.

Lava-flows. During some geological periods lava has welled up through enormous fissures in the earth's surface. Lava-flows of this type, some 6,000 feet thick, cover an area of about 200,000 square miles in the north-west part of the Deccan Plateau of India, and also form the Idaho Plateau of the North-West United States.

EARTHQUAKES

Volcanic eruptions are often associated with earthquakes, though it is probable that both phenomena have their common origin in deep-seated earth movements. Such movements, due to folding or faulting, may in themselves be slight, but the vibrations they set up are often very great.

The fold-mountain belt around the Pacific is a scene not only of many volcanic eruptions, but also of frequent earthquakes, like that which razed Yokohama to the ground in 1923, and the one in the Hawke's Bay District of New Zealand in 1931. On the other hand, some of the most disastrous earthquakes of recent times, such as the earthquake which utterly destroyed Quetta in 1935, have occurred in regions which, though now free from volcanic activity, lie on the margins of fold-mountain areas.

PLAINS

Plains are due to a variety of causes. *Peneplains* (*pene* = almost), such as most of Finland, have been formed by prolonged erosion. *Alluvial plains* have been built up by deposits brought down by rivers. The alluvial plain of the lower Mississippi is composed of silt spread by the river over the surrounding land during floods. Very similar are *deltaic* plains, like that of the Ganges-Brahmaputra, which have been formed of sediment deposited at the mouths of rivers to form a *delta*. In some cases, as for example that of the Po, the Tigris-Euphrates lowland, and the Plain of Hungary, a shallow

sea has been filled with river-borne deposits which have converted it into a plain. Many *coastal* plains, like that of the Eastern United States, have been caused by the uplift of the continental shelf.

DENUDATION

The process known as denudation, or the wearing away of the land, is continually going on. (1) Changes of temperature; (2) frost; (3) winds; (4) water, including rivers; (5) ice; and (6) the action of the sea are the chief causes of such erosion.

(1) **Changes of Temperature.** *Heat.* Hot desert regions, such as the Sahara, are subject to considerable daily and seasonal ranges of temperature. This is due mainly to lack of protective covering, which causes the bare ground to heat rapidly, when it is exposed to the fierce rays of the sun shining down from a cloudless sky, and also to become quickly chilled after sunset by radiation. The high temperatures cause the rocks to expand rapidly, for they are not good conductors of heat, and the various minerals they contain have different rates of expansion. At night very rapid cooling results in contraction at varying rates. Thus the alternate expansion and contraction causes the surface layers of the rocks to split and break off. The broken portions are scattered in all directions; smaller pieces are carried by the wind and ground down into grains of sand.

(2) **Frost.** Water, penetrating into the cracks of rocks, expands on freezing and tends to split the rock, causing pieces to break off. In mountainous districts, such fragments tumble down the slopes and collect together to form piles of loose rock known as *screes*. In the English Lake District, Wastwater is famous for its screes.

(3) **Wind** is an agent of denudation. When laden with sand it scours away the softer portions of cliff faces and other exposed rock surfaces. In certain dry areas in North America wind erosion has caused much damage. For instance, in the 'dust-bowl', the name given to that part of the High Plains suffering from dust-storms, the soil has been stripped away by wind and the land rendered desolate.

Wind is also a builder-up of the land. In desert regions, or along the coast, it heaps the sand into wave-like dunes. The loess plains of Northern China are composed of wind-borne material (see p. 308).

(4) **Water**, in the form of rain or rivers, plays a predominant part in wearing away the earth's surface.

Rain. The action of rain can be seen on any road after a shower

by observing the muddy water in the gutters; but obviously its effect is greatest in mountainous districts with a heavy rainfall. Rain-water contains carbon-dioxide, which is a powerful eroding agent of limestone. The water dissolves this soluble rock at the joints (cracks), causing it to weather into peaks and pinnacles of fantastic form. In limestone districts rivers often cut deep gorges, like the magnificent Tarn Gorge in South-West France, or Dovedale, a noted beauty spot in Derbyshire. Streams often disappear through sink-holes in the rock, flow underground for some distance, and

FIG. 15.

gush out at lower levels. As such streams cut their way deeper and deeper through the limestone, they form caves, of which Mammoth Cave in Kentucky, U.S.A., the Grottoes of Hahn in South Belgium, and the Cheddar Caves in the Mendips are noted examples. Pendants of stone, called stalactites, hanging from the roof, and corresponding pillars, called stalagmites, rising from the floor are beautiful and sparkling features of such caves. In some limestone districts rivers dissolve the limestone and expand into shallow lakes, known as *solution lakes*, such as Loughs Conn, Mask, and Corrib in Western Ireland. The name *karst* type, applied to limestone regions, is derived from the Karst district of Dalmatia (Yugoslavia), celebrated for this type of scenery.

Rocks like clay, shale, granite, and slates are impervious to water, but others such as limestone, chalk, and sandstone are porous. Rain, after sinking through porous rocks, often reaches an impermeable bed, along which it flows, emerging on a hill-side as a *spring* at the junction of the two types of rock (Fig. 15 A).

Springs also occur along lines of faulting (Fig. 15 B). In such cases the water descends through the porous strata until it reaches impermeable rock, over which it runs until it reaches a fault, where it is

checked. At this point it forms an underground reservoir. Pressure of the head of water in the strata above may force it to find its way to the surface as a spring. On the other hand, the water may remain imprisoned until tapped for a well. In certain parts of the world *artesian wells* are bored to obtain water lying in underground reservoirs at great depth below the surface.

FIG. 16.

Rivers. Running water is one of the greatest agents both of denudation and deposition. When rain falls, some evaporates, some sinks into the ground, and some runs over the surface in little rivulets which gradually unite to form a *collecting basin* whence a stream, draining the basin, issues to form a river. Such collecting basins may be seen in many districts.

In its mountain track a river flows extremely swiftly, cutting deeper and deeper into its valley, and carrying with it not only much sediment, but also rolling along its bed rocks and even boulders

of considerable size. As the rock fragments pound against each other they become smaller and smaller, while at the same time they help both to deepen and to widen the bed of the stream. In its middle course the gradient is usually less and the current consequently less swift. Thus the rocks and pebbles move along more slowly and together with sediment tend to be deposited on the bed.

As the river flows over still flatter land in its lower course, its erosive power is lessened and much sediment is dropped upon its bed, which is being continually raised. In cases like the lower Mississippi or the Po, the stream actually flows at a higher level than the surrounding country, which is protected from inundations by embankments. In flood times alluvium is spread over the lowlands, so helping to build up a flood plain.

In the lower part of its course, owing to the slowness of the current, the stream winds round obstacles instead of cutting through them, and meanders (see Fig. 16) over the plain, forming great curves and bends. The current eats into the outer, or concave, side, cutting away a steep bank or *bluff*. On the opposite, or convex, bank the current is much slower, the sediment is deposited, and the bank built up. In course of time the bends which the river has formed approach each other, and during floods the waters cut across the land between such bends, and by forming fresh channels shorten the river's course. A part of the former river bed is often left as a lake, which, on account of its shape, is called an *ox-bow lake* (Fig. 16, iii).

If the mouth of a river is tidal (i.e. an estuary), the currents scour its bed. In this way they carry the sediment away and, by depositing it over a considerable area, help to keep the channel free for shipping. When the river flows into a lake or a sea, like the Mediterranean, where the tidal range is small, its current is checked, and sediment is steadily deposited at the mouth, thus gradually building up an island which, owing to its resemblance to the Greek letter Δ , is called a *delta* (see Fig. 17). Despite the fact that their mouths are tidal, great

FIG. 17.

ivers, like the Orinoco, form deltas owing to the load of sediment they carry. In addition to the sediment brought down by a river, masses of floating vegetation, and drift carried by currents, also aid in building up the delta, across which in the course of time the river cuts *distributaries* to allow its waters to reach the sea.

How a River Valley is broadened. The typical river valley is V-shaped (see Fig. 18). It is being continually broadened by denudation, but the rate at which this takes place, compared with that at which the river erodes its bed, differs greatly in the various sections of the valley. In its mountain course the cutting-down force of the

FIG. 18. How a River Valley is Broadened.

river is much greater than the effect of wind, rain, and frost on the sides of its valley, which are usually steep. In the middle course the erosive effect of the river is lessened, and is more nearly equal to the lateral cutting of the sides of the valley, which is consequently somewhat broader. But in its lower course the lateral erosion of the valley is relatively much greater than the vertical cutting down of the river, which indeed now deposits rather than removes material. Thus, while the river builds up the lowlands, the sides of its valley are steadily broadened and their gradient lessened by weathering.

In arid districts, however, there is little or no rain to wear away the valley sides, and the principal erosion is that due to the river cutting its way deeper and deeper through the underlying strata. In such areas deep gorges, called canyons, are formed, of which the classic example is that of the Colorado river, in North America, which has helped to cut a canyon bordered by almost vertical cliffs, some 200 miles long, over a mile deep, and from 4 to 12 miles wide. In part, the formation of the Grand Canyon of the Colorado is due to the uplift of the surrounding plateau.

River Capture (Fig. 19). In their upper courses rivers not only deepen their valleys, but cut them back, thus causing their sources to move farther and farther from their mouths. As this retreating

process continues one river may ultimately *capture* the headwaters of another, causing the upper waters of the weaker stream to be diverted into those of the stronger. In this way the Trent captured the headwaters of a stream that once flowed into the Witham. In South America, the Cassiquiare, which flows into both the Orinoco and the Rio Negro, a tributary of the Amazon, provides an example of middle-stage river capture.

(5) **The Work of Ice.** During the Great Ice Age (the Pleistocene period) Northern Europe, including the British Isles as far south as the Thames, the north of North America, and possibly other

FIG. 19. River Capture.

regions, were covered by an Ice Sheet which spread over both lowlands and mountains, leaving only the highest peaks rising like islands above its glassy surface.

There were several Ice Ages. When the last Ice Sheet began to melt and disappear, it left behind masses of debris, or *drift*, which was sometimes heaped into low rounded ridges, and sometimes formed great sheets of boulder clay, like that covering a considerable portion of the British Isles, where it has weathered to form fertile agricultural land. In some areas the drift dammed up the normal outlets of valleys, causing the streams flowing into them to expand into lakes, known as *morainic dammed lakes*.

The Ice Sheet also transported great boulders and blocks of rock for considerable distances, and when it melted deposited them in regions quite different from their original homes. Boulders of this type, called *erratics* (or 'wanderers'), are found in many places once covered by the Ice Sheet. At the present time permanent ice and snow are found only in mountainous areas, or in high latitudes such as Greenland and the continent of Antarctica.

Glaciers. In the higher parts of mountain regions are numerous *snow-fields*, formed of accumulations of granular snow known as

névé, or *firn*. The lower layers of the snow are changed by pressure and freezing into solid ice which moves very slowly down the valley as a glacier. In the Alps the average rate of progress of such glaciers is not more than a foot a year. As the glacier moves it collects along its flanks rocks, stones, and other material known as *moraines*. When two glaciers unite, the moraine formed down the

FIG. 20. Section of a U-shaped Valley.

Dotted line A,A' shows pre-glacial valley before it was over-deepened by the passage of a glacier. BC, B'C' are the mountain slopes which rose above the glacier; AB, A'B' the shelves now covered with glacial debris forming pastures—the *alps*. Streams fall over A and A' into the main valley. P is the probable site of a power-station.

middle of the united glacier is called a *medial moraine*. When a glacier reaches the snow-line it melts and the rock waste is deposited as a *terminal moraine*, which usually stretches right across the valley. From the *snout*, or end, of the glacier streams descend to the valley beyond: the Rhine and the Rhone both flow out of the glaciers of the St. Gothard group.

U-shaped valleys (Fig. 20). Whereas the typical river valley is V-shaped, one in a recently glaciated region is usually U-shaped, for it has been *over-deepened* by the passage of a glacier. Such a valley has a flat floor and steep sides above which stretch the gentler slopes of tributary valleys. As the latter are said to hang over the main valley, they are known as *hanging valleys*. From these side valleys numerous streams descend into the main valley by waterfalls which

are often used to generate hydro-electric power (Fig. 20 *P*). At the head of many U-shaped valleys there are amphitheatre-like openings, known as *cirques*, or (in Scotland) *corries*, which were once filled by glaciers.

(6) **The Action of the Sea.** Most of us have watched the sea crashing with mighty force against the cliffs. So great is the power of the storm-breakers that they smash off big blocks of rock, as well as countless lesser fragments, pounding all into smaller and smaller pieces. Air in cracks and caves is imprisoned and driven inwards by such breakers. On the recoil, the compressed air rushes out and the resulting suction tends to loosen the rock. In this way cracks and caves are being continually enlarged, causing masses of rock to break away from the cliffs. Coastal erosion is mainly due to the action of the breakers. With each high tide the surf hurls pebbles and sand against the foot of the cliffs until their base crumbles away.

The exposed surfaces of the cliffs are subject to weathering, which helps to eat back their faces. In cases where cliffs are formed of porous rock, like chalk or sandstone, resting upon an impermeable rock like clay, rain-water soaks through to the underlying strata and, running along them towards the face of the cliff, undermines the whole structure, with the result that a landslide often occurs.

The more resistant rocks stand out as headlands and promontories whose ends are being constantly worn away. Sometimes masses of rock, cut off from the mainland by erosion, are left standing as *rock stacks*, such as the Needles, off the most westerly point of the Isle of Wight.

Pebbles, gravel, and sand are carried by currents and deposited on the beaches, especially in the bays. In this way the sea straightens out the coast-line; so its action is not merely destructive, but also constructive, for it helps to build up the land. In relatively shallow seas, currents often deposit, along the coast, sand, shingle, and silt in the form of banks or islands. In the English Channel, eastward-flowing currents, aided by breakers rolling in from the south-west, have caused a drift of beach shingle along the coasts of Southern England. The Chesil Bank, which connects Portland Island with the mainland, formerly a submarine ridge, is now covered with pebbles piled to a height of some 50 feet.

Along the east coast of England the southward drift of the currents has caused the mouths of a number of rivers to become blocked with sand, forcing them to seek fresh outlets. Thus the

original mouth of the Alde has been closed by a shingle bank, and the river now flows south for 10 miles, parallel to the coast, before entering the North Sea.

Somewhat similar cases occur along the Baltic coast of Germany, where shallow openings, called *haffs*, like the Frisches Haff, have been almost enclosed by sand spits, known as *nehrungs*, built up partly by debris carried eastward by currents, and partly of blown sand.

Along some low-lying tropical coasts, such as the east coast of Malaya, mangroves not only protect the land from erosion but assist in building it up. These curious trees spread by dropping their branches into the ground to form fresh roots. Silt brought down by rivers, or carried along by currents, as well as decayed vegetation trapped in the mass of branches and roots, helps to build up alluvial plains. Such plains are, however, usually unhealthy and retard the development of those coastal areas where they occur.

Coral formations also serve to protect the coast. As the coral polyp builds only in calm, clear, warm shallow salt water, this type of formation is confined to tropical or sub-tropical seas.

TYPES OF COAST-LINES

Coast-lines are relatively unstable. When the feature lines of the land run parallel to the coast, the latter is said to be *concordant*. When the coast cuts across the grain of the land, it is termed *discordant*. For example, the north coast of Spain, running parallel to the ranges of the Cantabrians, is a concordant coast. The south-east coast of England, which cuts across the grain of the North and South Downs and minor ridges, is a discordant coast. In cases where the grain of the land cannot be definitely related to the direction of the coast-line, the coast is described as *neutral*.

Some coasts are *rising*: others are *sinking*. The presence of *raised beaches* shows that elevation has taken place. As a general rule straight coasts are *rising*. Sometimes, as along the west coast of the United States, they are bordered by fold-mountains; but in regions where the continental shelf is broad they are low and flat, and in either case they have few good openings. Sinking coasts, on the other hand, are much indented, for the sea floods the lower ends of the valleys, often turning them into excellent harbours.

In places where mountainous discordant coasts have subsided, the ends of the valleys, which have been 'drowned' by the sea, form

I. THE WORK OF ICE

The photograph (*above*) shows the origin of a glacier from a sheet of inland ice seen in the background. The lateral moraines can be seen at the sides of the two glaciers, and the medial moraine (*bottom right*) where they unite (*Below*) Erratics on the Canadian prairies. These isolated rocks were transported for several hundreds of miles by the Ice Sheet which once covered the north of North America (see pp 29 and 389).

rias, like those found in south-west Ireland and north-west Spain. Such *rias* grow shallower and narrower towards their heads.

Fiords are long, narrow, branching openings, bordered by steep walls, which often extend far inland. There is some dispute as to their origin, but as they are found in recently glaciated regions it seems probable that river valleys, following lines of faulting, were subsequently deepened by glacial action during the Ice Age. Most fiords have a submerged bar across their mouths which is, however, too deep to be an impediment to shipping. They are of considerable depth, and, unlike *rias*, become deeper as one proceeds towards their heads. Fiord coasts are found in Norway, British Columbia, South-West Chile, South-West New Zealand, where they are called Sounds; and in North-West Scotland, where they are known as sea-lochs.

The type of coast-line has a considerable effect on the progress of a region. A discordant coast with its many bays and estuaries favours development. Such a coast is often a nursery of a seafaring people, like the Norwegians, many of whom turned from a rather inhospitable land to seek their livelihood on the ocean.

TYPES OF LAKES

Lakes are due to a variety of causes. In some cases their origin is relatively simple: in others it is complex. Among the chief types of lakes are the following:

(1) *Mountain Ribbon Lakes* are long, narrow, and usually very deep. Their formation is probably due partly to the work of rivers and partly to glacial action. Examples are Loch Tay and most of the larger lakes in the Scottish Highlands; Lake Geneva and other Alpine lakes. Smaller lakes of this type, of which many are found in Scotland, are known as *Rock Tarns*.

(2) *Solution Lakes*, such as Lough Allcn, on the Shannon, have been formed by the dissolution of limestone (see p. 25).

(3) *Rift Valley Lakes*, lying in the bed of a rift valley, include such as Lakes Tanganyika and Nyasa in Central Africa (see p. 22).

(4) *Morainic Dammed Lakes*. Loch Leven, in Fifeshire, and the Lower Lake of Killarney, in South-West Ireland, are examples of this type (see p. 29).

(5) *Crater Lakes*, as their name implies, occupy the craters of extinct volcanoes. Well-known examples include Lake Avernus, near Naples, and Crater Lake in Oregon, U.S.A.

(6) *Raft Lakes* are formed by the temporary damming up of the normal outlet of a river. Tributaries of the upper Nile are often dammed up by floating vegetation, called sudd, which converts them into lakes. Such lakes are short-lived, for owing to the high temperature they are exposed to great evaporation, while at the same time the river eventually finds an outlet through the sudd. In other cases the temporary barrier to the normal drainage may be caused by blown sand, ice, or lava flows.

(7) *Ox-bow Lakes* (see p. 27).

Lakes are, of necessity, temporary features of a region, for rivers (a) tend to fill them up by depositing sediment on their beds, and (b) by cutting down their outlet, lower their level.

The *uses of lakes* are many and varied. They tend to check floods, and so indirectly help to prevent great loss of life and material damage. Lake Constance checks the floods of the Rhine; Lake Geneva those of the Rhone; while in China, Lake Poyang reduces the floods on the Kan, a tributary of the Yangtze river. By causing them to deposit their sediment, lakes act as filters for rivers. The Rhine enters Lake Constance as a turbid river, but issues from it as a clear stream. Vast sheets of water, like the Great Lakes, provide valuable means of transport. The fisheries of such lakes are of considerable economic importance. In many countries natural and artificial lakes are used as reservoirs. Lakes also supply water for *irrigation*. In some cases they are tapped for hydro-electric power. If lakes are of considerable size, like the Great Lakes, they increase the rainfall and moderate the temperature of surrounding areas.

EXERCISES

1. What do you understand by the terms (a) rock, and (b) mineral? Name the three main groups of rocks. Describe briefly how each has been formed and give examples of each.
2. What are the chief causes of the formation of lake basins? Illustrate your answer by examples.
3. How are fold mountains formed? Give examples. Why are such areas often associated with volcanic activity?
4. Write short notes on (a) canyons, and (b) U-shaped valleys. In each case draw a contour map of the valley. Illustrate your answer by examples.
5. What do you mean by *river capture*? Give examples and diagrams.
6. With the help of diagrams explain four of the following terms: hanging valley, terminal moraine, fiord, ria, continental shelf, raised beach.

CHAPTER IV

THE ATMOSPHERE

General Characteristics of the Atmosphere. The air is composed mainly of nitrogen (78 per cent.) and oxygen (21 per cent.), with small proportions of carbon dioxide, water gas (water vapour), and rarer gases like argon, and neon, made familiar to us by its use for neon signs. The nitrogen serves to dilute the oxygen which is essential for living organisms. Plants absorb carbon dioxide, extract the carbon, and return the oxygen to the air. The water vapour present in the air is of great importance, especially as regards its relation to weather and climate.

The belt of air which envelops the earth forms the atmosphere. It is estimated that the atmosphere is 100 or possibly 200 miles thick, but nine-tenths of the air composing it is found within 12 miles, and half within $3\frac{1}{2}$ miles of the earth's surface. We are concerned only with the lower layer, or *troposphere*, which extends for some 6 miles. The upper layer is known as the *stratosphere*.

The air nearest the earth is compressed by the weight of the remainder of the atmosphere resting upon it. So great is the pressure that at sea-level it is equal, on an average, to 14.7 pounds to the square inch, but as this pressure is exerted equally in all directions we do not feel it. Such pressure, expressed as a height, is measured by a barometer. One of the simplest kinds is shown in Fig. 21. The long branch of the tube is closed to the air. The short branch is open, and the pressure of the air at *P* supports a column of mercury. At sea-level the pressure of the atmosphere will support a column of mercury 29.9 inches (or 760 mm.) high. It should, however, be clearly understood that, even at sea-level, pressure varies. If the pressure be low, the height of the barometer may stand at only 28 inches; if the pressure be high, the barometer may show a reading of 31 inches. Pressure decreases with increasing elevation, for the air naturally becomes less compressed as the weight of the atmosphere resting upon it decreases. At ordinary elevations the mercury in the barometer falls 1 inch for every 900 feet of ascent,

FIG. 21.

but at greater heights the pressure does not diminish nearly so rapidly. At an elevation of $3\frac{1}{2}$ miles the pressure is half that at sea-level. This decreasing pressure, due to rarefied air with a corresponding decrease in the proportion of oxygen, is a cause of great discomfort to mountaineers. Lack of oxygen causes dizziness, headaches, sickness, and nose-bleeding. It also tends to make the brain sluggish, and may even result in unconsciousness. Climbers, such as those who attempt to conquer Everest, often wear oxygen-masks at higher altitudes. Such masks are also worn by airmen flying at high altitudes, e.g. 30,000 feet. Stratocruisers used by civilian air lines on long-distance flights, and certain types of military aircraft, are fitted with pressurized cabins in which the air is maintained at a pressure equal to normal atmospheric pressure.

Pressure and Winds. *Wind is air in motion.* The chief cause of wind is difference in atmospheric pressure. When air is heated it expands, becomes lighter, and rises. When air is cooled it contracts, becomes heavier, and falls. One of the main reasons for differences in pressure is unequal heating of the air. Pressure varies greatly over different parts of the earth's surface, and also from day to day in any particular district. But there are certain permanent belts of high and low pressure over the earth's surface. From the high pressure belts the air, of course, flows outward to the regions of low pressure.

(1) Around the *Equator* there is a region of *low pressure* with rising currents of warm moisture-laden air. Such ascending air currents, over hot regions, are called convection currents. The rising air over the Equator, on reaching the upper layers of the atmosphere, flows outwards towards higher latitudes, where it feeds the down-settling air of the high pressure belts.

(2) Low pressure areas also occur about latitudes 60° N. and 60° S., that of the North Atlantic being known as the *Icelandic Low*.

(3) About latitudes 30° N. and 30° S. there are permanent belts of *high pressure* from which the air flows towards the low-pressure belts (a) round the Equator, and (b) those round 60° N. and 60° S. Recent exploration has also shown that the polar regions are areas of moderate high pressure, and that this is sufficient to cause out-flowing surface winds.

Both the high-pressure and the low-pressure belts are regions of

calms. The calms about 30° N. and 30° S. are known as the *Horse Latitudes*. Those round the Equator are called the *Doldrums*.

It should be noted that there are two major but closely related sets of winds, namely (1) those of the upper atmosphere blowing from the equatorial region towards the high-pressure belts, and (2) the surface winds blowing from the high-pressure belts to those of low pressure.

The Wind Belts. Owing to the rotation of the earth, the winds do not blow due north and south from the belts of high pressure to those of low pressure, but are deflected. In this deflection they obey

FIG. 22.

Ferrel's Law which states that: *Any moving body on the earth's surface, including a current of air, tends to be deflected, the deflection being to the right in the northern hemisphere, and to the left in the southern hemisphere.* [This law should be learnt by heart.]

There are four well-marked belts of surface winds. (1) The *westerly variables*, and (2) the *brave west winds*, which blow from the high-pressure belts round about latitudes 30° N. and 30° S. respectively, to the low-pressure belts about 60° N. and 60° S. (3) The *north-east trades*, and (4) the *south-east trades* which blow from the high-pressure belts round about 30° N. and 30° S. respectively towards the Equatorial Belt. In addition, there are the winds blowing outwards from the polar high-pressure regions towards the low-pressure belts about 60° N. and 60° S.

The diagram (Fig. 22) shows the position of these belts when the

sun is overhead at the equator. The wind belts move north and south with the apparent movements of the sun. But though the position of the noon overhead sun varies from $23\frac{1}{2}^{\circ}$ N. on June 21st to $23\frac{1}{2}^{\circ}$ S. on December 22nd, the belts of winds and calms move on the same direction only approximately 5° .

The unequal distribution of land and water affects, to some extent, the arrangement of the wind belts. Large bodies of water are not subject to such great changes of temperature as masses of land. Thus in the Southern Hemisphere, where a much larger expanse of the

FIG. 23.

earth's surface (especially south of 30° S.) is covered with water than in the Northern Hemisphere, the winds are more constant. The brave west winds are stronger and more regular than the corresponding westerly variables of the Northern Hemisphere.

The presence in summer of low-pressure regions in the interiors of continents like North America and Asia is due to their greater heat relative to the surrounding oceans. This affects the direction of the winds. In winter the interior of these continents are regions of great cold and high pressure, and this too alters the direction of the winds by causing them to blow outwards from the land towards the oceans.

Land and Sea Breezes. These local winds, due to the unequal heating of land and water, and consequently of the air above their surfaces, well illustrate the relation between pressure and winds. During the day the land becomes very much hotter than the sea,

with the result that there is marked low pressure over the land. Thus the heavier and denser air over the sea flows towards the land (Fig. 23). At night these conditions are reversed. The land rapidly loses its heat and becomes an area of high pressure. During the day the sea has gradually been growing warmer, and as it does not lose its heat nearly so quickly as the land, it remains warm for a longer time, and the air over it, being relatively warm and light, forms an area of low pressure. Thus at night, heavy cool air blows from the land to take the place of warm air rising over the sea. Land and sea breezes are most frequent during fairly settled weather.

The *Monsoon*, or seasonal winds, of south-east Asia, which are especially well marked in the sub-continent of India, may be regarded as land and sea breezes on a large scale, in which the period is a year instead of a day (see p. 262).

EXERCISES

1. What do you mean by an area of high pressure? Show, by means of a diagram, the position of the chief high- and low-pressure belts over the earth's surface.
2. Illustrating your answer by a diagram, give a general account of the chief planetary winds.
3. Write short notes on the doldrums, horse latitudes, Ferrel's Law, and the troposphere.
4. Describe, giving your reasons, the course of a sailing ship travelling from Australia to England. Give a map to illustrate your answer, and on it show the direction of the prevailing winds.
5. Trading dhows (sailing boats) make regular journeys between the Persian Gulf and Zanzibar. State, giving your reasons, at what season you think such boats would sail from the Persian Gulf to Zanzibar, and at what season you think they would make the return journey.

CHAPTER V

THE OCEANS

If we look at a globe we shall see that a great proportion of the earth's surface is covered with water which forms a connected expanse divided into oceans ; and that, of the land area, by far the larger part lies in the Northern Hemisphere. It is estimated that 72 per cent. of the surface of the globe is covered with water, which fills

the deep hollows in the earth's crust and separates the continental masses.

FIG. 24. Continental Shelf.

The edges of the continents are covered with shallow waters, not more than 100 fathoms deep, beneath which lies the *Continental Shelf*. The slope of the shelf is

usually gentle, but beyond the 100-fathom line it descends steeply to the bed of the ocean. This line, called the *Continental Edge*, marks a probable original coast-line. The steep slope beyond is known as the *Continental Slope* (Fig. 24).

In most areas where the coast of a continent is bordered by mountain ranges the continental shelf is narrow, its edge lies close to the shore-line, and its slope continues the line of the mountains. But where the land slopes gently to the shore-line the gradual gradient is continued beneath the sea, and the shelf is broad. Much of the waste of the land, brought down by rivers, is spread over the continental shelf, where, directly or indirectly, it provides food for marine life. This is one of the reasons why the world's chief fishing-grounds, such as the Grand Banks of Newfoundland and the North Sea, are found where shallow waters cover a wide continental shelf.

THE OCEANS

Antarctica is surrounded by the *Southern*, or *Antarctic Ocean*, which beyond latitude 60° S. merges into the Pacific, Atlantic, and Indian Oceans.

The *Pacific*, greatest of all oceans, covers a third of the earth's surface, its total area being greater than that of all the dry land. Its basin contains some of the greatest known depths. So deep are some portions that if Mount Everest were sunk therein the summit would not only be submerged, but would lie 3,000 feet below the surface. The waters of the Pacific wash the western coasts of the Americas and the eastern coasts of Asia and Australia. But though open to the Southern Ocean on the south, it is almost closed on the north, where the narrow Bering Strait, separating North America from Asia, links it with the Arctic Ocean.

The Pacific is bordered by fold-mountains whose weakened crests contain numerous active and extinct volcanoes. This mountain girdle includes the Rockies and Andes of the Americas, and the island-fringe of Asia, which represents the higher portions of a partially submerged fold-mountain range.

The countless islands strewn over the south-west Pacific can be divided into *High* volcanic islands, such as the Hawaiian Islands, Tahiti, and Samoa; and *Low* coral islands, like the Marshall and Gilbert Islands. These islands yield a variety of tropical products and some are important as naval and air bases and as cable and wireless stations.

The *Indian Ocean* is bounded by Africa on the west, by India and Indo-China on the north, and Australia and the East Indies on the east. Ceylon and Madagascar are continental islands which are probably the remains of an ancient continent.

Though the *Atlantic* is slightly less than half the size of the Pacific, yet so many great rivers flow into it that it receives half the drainage of the world. On the west it washes the shores of the Americas, on the east those of Europe and Africa separated by the narrow Strait of Gibraltar leading to the Mediterranean. From the Southern Ocean the Atlantic narrows somewhat towards the Equator, where the western wing of Africa is separated from the most easterly point of South America by a passage, some 1,500 miles wide, crossed by the air route from Western Europe to South America. Of all oceans the Atlantic is the most important. Round its coasts and those of its subsidiary seas, such as the North, the Baltic, and the Mediterranean in the east, and the Gulf of Mexico in the west, stand most of the world's great ports, linked by trade routes more frequented than those of any other ocean.

The *Arctic* lies to the north of North America and Eurasia. It is connected with the Atlantic by a wide passage, in the midst of which stands Iceland; and which is defined by Greenland on the west and Scandinavia on the east. Northward the Arctic extends across the frozen seas surrounding the North Pole to the Pacific, with which it is linked by the Bering Strait.

THE BED OF THE OCEAN

The average depth of the ocean is 12,500 feet, compared with the average height of the land, which is about 2,500 feet. Protected from erosive forces, which play so great a part in moulding the surface of the land, the greater part of the deep-sea plain is stated to be nearly level, a feature of some practical importance, for it has facilitated the laying of submarine cables. In places, however, earth movements have caused the formation of submarine ridges and vast hollows, called deeps. The greatest known depth is that of the Marianas Trench in the Pacific, where a depth of 35,800 feet has been recorded. Other deeps in the Pacific are the Albatross Deep, south of the Aleutian Islands; the Tuscarora Deep, south-east of the Kurile Islands; the Nero Deep, east of Guam; the Penguin Deep, east of the Kermadec Islands; the Mindanao Deep, east of the Philippines; and the Atacama Deep, off the south-west coast of South America. In the Atlantic, a depth of 30,246 feet has been recorded in the Puerto Rico Trench, 80 miles north of Puerto Rico.

Among the best-known ridges is an S-shaped ridge running from north to south through the mid-Atlantic. In the North Atlantic it is known as the Dolphin Ridge, and in the South Atlantic as the Challenger Ridge.

SALINITY OF THE OCEANS

Though sea-water is always salt, the percentage in it varies. In the great oceans every 1,000 parts of sea-water contains on an average 35 parts of dissolved salts, but in some areas this proportion is as high as 37 and in others as low as 30 parts per thousand. When sea-water is evaporated the greater part of the solid matter left behind consists of common salt. In certain warm countries, like India, salt is obtained by allowing sea-water to evaporate in shallow lagoons.

Rain-water is free from salt. In regions where the rainfall is exceptionally heavy, the surface salinity of the ocean is less than in

areas of lower rainfall. Ice contains relatively little salt, and so the water from icebergs reduces the salinity of the seas in areas, such as the North Atlantic, where they melt.

The surface salinity of the ocean in the Equatorial Belt is relatively low (35 to 34 per thousand) owing to the addition of fresh water through heavy rains. In the high-pressure belts around the Tropics of Cancer and Capricorn, the surface waters of the ocean are very salt (36 parts per thousand) on account of the great heat and consequent evaporation, and the comparatively low rainfall. In higher cooler latitudes the surface waters are comparatively fresh, as there is less evaporation and more rain than in the region around the Tropics. In the North and South Atlantic, for example, the surface salinity varies from 35 to 32 per thousand. It is lowest (32 per thousand) in the seas between Labrador and Baffin Land on the west and Greenland on the east, where water from melting icebergs increases the freshness of the sea-water. For the same reason the surface salinity in the Polar Seas is only about 30 per thousand.

Very high salinities are found in enclosed or partially enclosed seas subject to great evaporation. In the Red Sea and the Mediterranean the surface salinity is 40 per thousand, while the waters of the Dead Sea actually contain 225 parts of dissolved salts per 1,000.

On the other hand, in seas like the Baltic, fed by vast quantities of river-water, and not subject to great evaporation, the salinity is very low. In the south it is about 8 per thousand, while in the Gulf of Bothnia it is as low as 2 per thousand. This freshness of the water partly explains why the Baltic freezes more readily than the Mediterranean, which has relatively few large rivers entering it, and which, on account of its lower latitude, is subject to greater evaporation.

TEMPERATURE

The surface temperature of the ocean diminishes from the equator to the poles. In equatorial regions it is about 80° F. In partially enclosed tropical and sub-tropical seas, like the Gulf of Mexico, the waters are somewhat warmer than those of the open ocean in similar latitudes, but in seas in higher latitudes, like the Baltic, temperatures are less than in corresponding latitudes in the open ocean. Temperatures decrease with increasing depth below the surface. This fall is usually rapid at first, but diminishes with greater depth, and below 6,000 feet temperatures are fairly constant at about 35° F.

OCEAN CURRENTS

Currents of the Atlantic. The North-East and South-East Trade Winds drive two currents, known as the *North Equatorial* and the *South Equatorial*, across the Atlantic from the shores of Africa towards the Americas. The North Equatorial divides into two portions on approaching the West Indies: one branch running north of these islands, the other through the Caribbean Sea into the Gulf of Mexico. The South Equatorial Current divides on reaching the projecting coast of South America: one branch runs south as the warm *Brazil Current* along the coast of Brazil, but on reaching the latitude of the westerly winds it is driven east to the shores of Africa. It then turns north and, as the cool *Benguela Current*, flows north along the west coast of Africa and rejoins the South Equatorial Current. The northern branch of the South Equatorial Current flows along the north coast of South America, through the Caribbean Sea (where it reinforces the North Equatorial Current), and into the Gulf of Mexico. The piling up of waters off the north coast of South America by the equatorial currents causes a counter current, known as the *Guinea Current*, to run eastward into the Gulf of Guinea, around which it flows until it rejoins the South Equatorial Current.

The heaping up of waters in the Gulf of Mexico causes the *Gulf Stream* to flow out through the Florida Strait. This warm current moves at a speed of some 4 miles an hour along the east coast of the United States until it reaches Cape Hatteras, where it spreads out and merges into the *North Atlantic Drift* which, under the influence of the westerly variables, flows north-eastward towards the shores of North-West Europe. Some of the waters of the North Atlantic Drift are deflected south off the coast of the Iberian Peninsula and flow along the north-west coast of Africa as the cool *Canaries Current*, which ultimately merges into the North Equatorial Current.

The waters passing into the Arctic Ocean from the Northern Atlantic cannot go on accumulating there indefinitely, and cold currents flow along both sides of Greenland southward into the Atlantic. That known as the *Labrador Current*, which flows between Greenland and Baffin Land, is partly responsible for the severe winters of the St. Lawrence Region and the freezing up of the approaches to that estuary. As the Labrador Current flows southward its cold, dense waters sink beneath those of the Gulf Stream.

The mixing of warm moist air over the Gulf Stream with the cold air over the Labrador Current is responsible for the frequent fogs in

FIG. 25. Currents of the Atlantic.

the neighbourhood of the Grand Banks of Newfoundland and at the mouth of the St. Lawrence. The icebergs brought down by the Labrador Current are a menace to shipping. In the south-west of the North Atlantic a great area of comparatively calm water, surrounded by swirling currents and drifts, forms the *Sargasso Sea*, where vast quantities of floating seaweed are continually collecting.

Currents of the Pacific. In the Pacific, under the influence of the trade winds, the *North Equatorial* and a *South Equatorial Current* flow westward from the shores of the Americas towards Asia and Australia. Between them, a counter current, the *Equatorial Counter Current*, due to the piling up of waters in the west, flows eastward towards the Americas. The *North Equatorial Current*, on

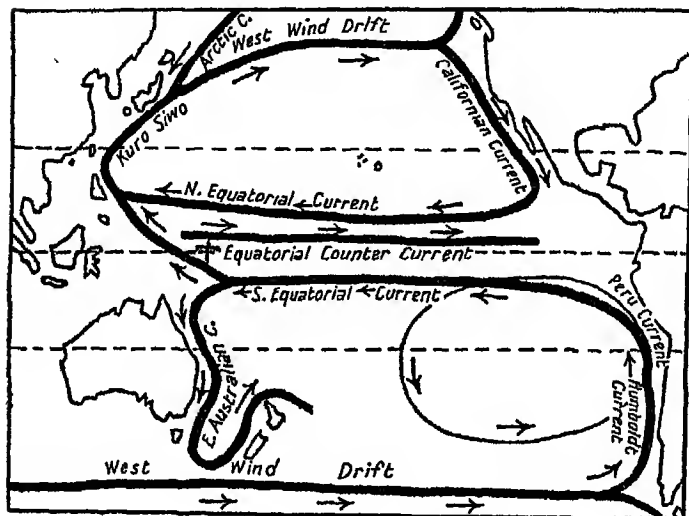

FIG. 26. Currents of the Pacific.

reaching the East Indies, turns north and flows along the east coast of Asia as the warm *Kuro Siwo*, or *Japan Current*. Off the east coast of Japan, it is driven by the westerly winds eastward towards North America, where the greater part turns south, passing along the west coast of the continent as the cool *Californian Current*, which finally merges into the *North Equatorial Current*. The *South Equatorial Current*, on reaching Australia, divides into two. The more northerly branch flows north-west to join the *North Equatorial Current*. The southerly branch passes along the east of Australia and Tasmania as the warm *East Australian Current* whence, under the influence of the brave west winds, it flows east and circulates on both sides of New Zealand. The brave west winds drive the *West Wind Drift*

castward across the Southern Pacific. A portion of this drift turns north on reaching the west coast of South America, and runs along the coast of Chile as the cold *Humboldt Current*, which off the coast of Peru (*Peru Current*) merges into the South Equatorial Current.

Currents of the Indian Ocean. In the south of the Indian Ocean the circulation resembles that of the South Pacific. A *South*

FIG. 27. Currents of the Indian Ocean.

Equatorial Current turns south off Madagascar and, as the *Agulhas Current*, passes along the south-east coast of South Africa. It then flows east and merges into the *West Wind Drift*. Part of this current, the cool *West Australia Current*, on reaching Australia, turns north.

In the north of the Indian Ocean the currents depend on the direction of the monsoon winds. In summer the south-west monsoon winds drive the waters of the *Monsoon Drift* in a clockwise direction around the Arabian Sea and the Bay of Bengal, whence they pass through the Strait of Malacca into the Pacific, reinforcing the *Kuro Siwo*. In winter, under the influence of the North-East Monsoon, the currents are reversed. They now flow in a counter-clockwise direction around the Bay of Bengal and the Arabian Sea, where the *Monsoon Drift*, on reaching the west coast of Africa, flows south, joins the *Mozambique Current* passing between Madagascar and the mainland, and then merges into the *Agulhas Current*.

TIDES

Every one who visits the sea is familiar with the tides. Twice a day the water rises: twice a day it recedes. Thus there is a space of some 12 hours (actually, on an average, 12 hours 25 minutes) between each high, or flood tide, and the same interval between each low, or ebb tide.

Tides are caused by the gravitational attraction—the 'pull'—of the moon on the earth, sometimes assisted by, and sometimes hindered by the sun. But, owing to the fact that the moon is so much nearer to the earth than the sun, its tide-raising effect is more than twice as great (the ratio is about 9 : 4) as that of the sun.

The liquid covering of the earth is much more affected than the solid portion. The water on the side of the earth nearest the moon is heaped up into a great wave, with a corresponding wave on the opposite side.

At new and full moon, when the sun, moon, and earth are practically in a straight line (Fig. 28 A), the attractive force of the sun increases that of the moon, thus causing tides that are higher and lower than the average. Such tides are called spring tides, and they occur, of course, twice in a lunar month.

When the moon is in its first and third quarters, the attractive force of the moon is exerted at right-angles to that of the sun and, as the two bodies are now opposed to each other, the tide-raising effect of the moon is lessened (Fig. 28 B). When this happens the high tides are not so high; the low tides do not recede so far, and there is less difference between high and low water. Such lesser tides are called neap tides. (How often do they occur?) The actual conditions described above are, of course, modified to some extent by the uneven distribution of land and water on the earth's surface.

In the open ocean the tides are not a striking phenomenon. The water moves up and down, but the rise or fall is limited to a few feet. There is a much greater difference between high and low tide in shallow seas, such as the North Sea, which are open to the ocean.

Southampton has double high tides. Formerly this was thought to be due to the fact that the tidal wave advancing up the English Channel divided on reaching the Isle of Wight. But recent research has shown that there is as yet no satisfactory explanation. Both

Bournemouth and Weymouth also have double high tides, as well as certain places on the opposite side of the English Channel.

In funnel-shaped estuaries, such as the Severn or the Bay of Fundy, the tidal wave passing up a rapidly narrowing opening has

FIG. 28. A. Spring Tides at New Moon. B. Neap Tides.

to accommodate itself to a smaller and smaller area, with the result that its amplitude steadily increases. In the Bay of Fundy the tidal range, or the difference between high and low water, is, during spring tides, sometimes as much as 70 feet, while in the Severn estuary it reaches some 40 feet. 'In some instances this action is so marked as to produce a crest-fronted wave, known as the *bore* on the Severn and as the *eagre* on the Trent.' These waves attain a height

of 3 or 4 feet, but the bore on the Yangtze-Kiang is as great as 12 feet high. In bottle-shaped estuaries, such as the Mersey, Portsmouth Harbour, and the Tagus, conditions are reversed, the tidal range is less than in funnel-shaped estuaries, and the strong currents passing through the narrow neck tend to scour the channel and keep it deep. The flood tide, by deepening estuaries, is advantageous to shipping, for (a) it makes it possible for vessels to travel farther up the estuary than would otherwise be the case, and (b) strong currents, by helping to keep channels free from silt, prevent deltas being built up, or sediment deposited.

In almost enclosed seas, like the Mediterranean, the tidal range is not more than 2 or 3 feet. Hence there are few strong currents to keep the mouth of the rivers free from silt, and, as we have seen, deltas are formed. Thus in the Mediterranean no important ports are actually situated on the rivers, though a number, like Marseilles, stand at the mouths of valleys which form channels of communication.

EXERCISES

1. The surface salinity of the ocean in the Equatorial Belt is 34 per thousand, around the Tropics of Cancer and Capricorn 36 per thousand, off Labrador 32 per thousand; while in the Baltic it is as low as 8 per thousand, and in the Dead Sea as high as 225 per thousand. Account for these differences.
2. What is the *continental shelf*? Discuss its practical importance, illustrating your answer from the seas round the British Isles.
3. What are the chief causes of ocean currents? Draw a sketch-map showing the chief currents of the Pacific Ocean.
4. Describe the general direction of the principal currents of the N. and S. Atlantic Ocean, showing the relation of the currents to the prevailing winds.
5. Name (a) *two* openings with exceptionally high tides, (b) *two* ports having double high tides, and (c) *one* sea where the tidal range is extremely small. (d) How may tides and tidal currents affect human activities?

CHAPTER VI

WEATHER AND CLIMATE

Weather may be defined as the condition of the atmosphere at any place at a particular time. The average weather conditions determine the *climate*. Humidity, temperature, elevation, distance from the sea, ocean currents, atmospheric pressure, and prevailing winds combine to affect the climate of a region.

HUMIDITY

Evaporation is the means by which water is drawn off, as invisible water vapour, from oceans, seas, lakes, rivers, and other exposed moist surfaces. Warm air can contain more moisture than cool air. *Humidity*, the term used to express the dampness of the atmosphere, is due to the presence of water vapour. When the air contains as much water vapour as it can hold it is said to be *saturated*. When saturated air is cooled *condensation* takes place, and some of the water vapour becomes visible as clouds, &c. The proportion of water vapour in the air, compared with the maximum it can hold at the same temperature, is known as the *Relative Humidity*. In equatorial regions it is not so much the high temperature which causes discomfort to white people as the high relative humidity.

Formation of Dew and Hoar Frost. Dew is caused by the condensation of water vapour on the cold ground during the night. Some of this moisture is obtained from the air itself, but the greater part rises into the air through blades of grass and from the roots of plants. The temperature at which such condensation takes place is called the *Dew Point*. When this occurs below freezing-point, then hoar frost is formed instead of dew.

Clouds, Fog, Mist, and Snow. The air contains tiny particles of dust around which the water vapour condenses as minute drops of liquid water. When condensation takes place at some distance from the ground, clouds are formed. If it takes place near the surface the result is usually *mist* or *fog*. The layer-like clouds often seen on the horizon at sunrise and sunset are called *stratus* clouds. The light wispy *cirrus* clouds, formed high in the sky, are due to low

temperatures which cause condensation to take place in the form of ice crystals. The heaped up clouds, looking rather like masses of cotton wool, called *cumulus*, are caused by currents of rising air. The black rain-clouds are known as *nimbus*. When water vapour is condensed at a temperature below freezing point it forms snow.

Rain. As the minute drops of water which form the clouds grow

FIG. 29. Relief Rains.

FIG. 30. Convictional Rains.

larger they fall to the earth as rain. Rainfall is caused by the cooling of saturated air.

(1) When winds blow from warmer to cooler latitudes they tend to cause rain.

(2) When moisture-laden winds are forced up to a higher level by mountains they rise into regions of less pressure, and on expanding lose much of their heat. As a result of this cooling some of the moisture in them is condensed, falling on the windward side of the mountains as rain. Such rains are known as *Relief Rains* (Fig. 29).

On descending the opposite side of the mountains, the winds, which have lost much of their moisture, tend to become still drier, for, as they contract and are warmed in their descent, they absorb rather than deposit moisture. The leeward side of such mountains is said to lie in their *Rain Shadow*.

(3) In equatorial regions, ascending air currents, rising into cooler regions, cause *Convictional Rains* (see p. 447) (Fig. 30).

(4) Heavy rains accompany cyclones (see p. 58).

Rainfall is measured by a rain-gauge which records the amount in inches. When we say an inch of rain has fallen, we mean that if none had been lost, and if the ground were quite flat, the latter would be covered with water to a depth of 1 inch.¹ To obtain a rainfall record, the monthly or yearly amounts are noted over a period of years, and the results added together and divided by the number of months or years during which records have been taken. Note that 1 foot of snow is equivalent to 1 inch of rain. The annual rainfall varies, of course, in different regions. Its value to plant life depends on latitude, but even more important than the total amount is its seasonal distribution.

TEMPERATURE

Of all climatic factors temperature is the most important. Deficient rainfall can, under favourable circumstances, be remedied by irrigation. Except on a small scale, the effect of great extremes of heat and cold cannot be overcome. Temperature affects man's food, crops, dress, and the type of dwelling he builds.

Temperature is measured by a thermometer. There are various kinds, but the one usually used in the British Isles is that with the Fahrenheit scale. In this scale, the freezing-point of water is 32° and boiling-point is 212°. To keep a temperature record, the maximum and minimum temperatures are added together, and the total divided by 2: the figures thus obtained given the mean temperature. If the mean temperatures for every day in the month are added together, and the result divided by the number of days in the month, the mean monthly temperature is obtained.

How the Earth's Surface is Heated. When the surface of the earth is warmed, the air nearest the ground is heated by contact, and this heat is passed on to the layers above, partly by conduction and

¹ 1 inch of rain = 100 tons of water (approximately) per acre.

partly by convection. In a similar way, when the ground is cold, the effect passes from the lower layers of the air upwards. Pure dry air allows the sun's rays to pass through it with little loss of heat; but the presence of clouds, water vapour, dust, and carbon-dioxide causes loss of heat during their passage through the atmosphere.

The earth's surface is warmed by the rays of the sun. The more directly the sun's rays shine down upon the surface, the less portion

FIG. 31.

of this surface have they to heat, and the greater their warming power. When the rays are slanting they spread out over a greater portion of the surface: thus each part receives less heat than if it were under the direct vertical rays. The sun is always more or less overhead in the zone that lies around the Equator, upon which its rays always shine down more or less directly. The farther one travels towards the polar regions, the less direct are the solar rays, and the less powerful is the heat they give. In higher latitudes, too, the rays have to pass through a thicker layer of the atmosphere, thus losing more heat than they do when travelling through thinner layers in lower latitudes. Fig. 31 shows two equal bundles of solar rays. Note that they have a smaller portion of the earth's surface to heat at CD, a region in the tropics, than at AB, nearer the poles, where

their heat is less concentrated because spread over a larger area. The temperature of a place depends mainly on latitude, but partly on elevation.

Influence of Altitude on Temperature. Temperature decreases 1 degree for every 300 feet above sea-level. This decrease is largely due to the fact that the rarefied air, found in elevated regions, absorbs less heat than the denser air at lower levels.

An interesting phenomenon, known as *inversion of temperature*, is sometimes experienced in mountain regions, where at times the temperature is less in the valleys than at greater heights. In winter when the weather is clear and calm, the cold heavy air, on account of its weight, flows down the mountain sides to the bottoms of narrow valleys, which thus become increasingly cold. At night the effect is increased, for owing to radiation, the layers of air near the ground become colder and so the air does not rise and mingle with the lighter layers above. But as soon as calm is succeeded by windy weather, the different layers of air mix and normal temperature conditions follow. This inversion of temperature accounts, in part, for the fact that in mountain regions villages are usually situated on the slopes of the hills, especially those slopes facing south (in the Northern Hemisphere), rather than on the valley floors.

The Influence of the Ocean on Temperature. Land heats more quickly than water, and also loses heat much more rapidly. Consequently, though the waters of the ocean take longer to heat than the land, they do not lose their heat nearly so quickly and are not subject to such rapid changes of temperature. In summer the winds from the ocean are cool, but in winter they are relatively warm. Hence in the temperate zones, the interiors of continents, lying as they do far from the sea, have hot summers and very cold winters. Such a type of climate is known as a *Continental Climate*. On the other hand, islands and continental margins where the prevailing winds blow on-shore, have a *Maritime* or *Insular Climate*. In summer cool winds blowing from the sea temper the heat, in winter warm winds from the ocean moderate the cold.

The Effect of Ocean Currents on Temperature. Ocean currents, by warming or cooling the winds blowing over them, affect the temperatures of adjacent lands. The warm North Atlantic Drift raises the winter temperatures of North-West Europe, especially those of the British Isles and Norway, forming a winter Gulf of Warmth.

Prevailing Winds. We have already seen (a) that the chief cause of wind is difference in atmospheric pressure; (b) that winds blow from regions of high pressure to those of low pressure; and (c) that there are well-marked prevailing winds in different regions of the world. Such winds have a close relation to both rainfall and temperature. In the British Isles, for example, the prevailing south-west winds, blowing from the Atlantic Ocean, (a) cause heavy rain in the mountainous west, and (b) render the temperature more equable by (i) reducing it in summer, and (ii) raising it in winter. In Northern Chile, the prevailing south-east trade winds blow off-shore, or parallel to the coast, throughout the year, with the result that this part of the country forms the rainless Atacama Desert.

ISOTHERMS

Isotherms (Greek *isos* = equal, *thermos* = heat) are lines, drawn on a map, joining places of equal temperature, such temperatures being first of all reduced to sea-level. Such reduction is, of course, made for the purpose of comparison. Isothermal maps are easy to memorize, but it is necessary to remember that, except in the case of a place situated at sea-level, they do not show the actual temperature. The latter is obtained by subtracting from the temperature, as shown by the isotherm passing through the place, 1 degree for every 300 feet of height.

Example. On an isothermal map of Canada, Calgary (3,389 feet) lies almost on the July isotherm 70° F.

July temperature at Calgary (to nearest degree)

$$\begin{aligned} &= 70 - \frac{3,389}{300} \\ &= 70 - 11 \\ &= 59^{\circ} \text{ F.} \end{aligned}$$

In most atlases the isothermal maps show the January and July temperatures, because these months are usually those with the greatest extremes of temperature and, moreover, may be taken as typical of the winter and summer conditions.

On some maps actual temperatures are shown by appropriate colouring or shading.

Temperature Maps of the World. A number of outstanding facts about the January and July Temperature Maps of the world

should be noted. We must remember, however, that while January is a winter month in the Northern Hemisphere, it is a summer one in the Southern Hemisphere (Figs. 32 and 33).

(1) In winter, the isotherms bend towards the Equator over the land and towards the Poles over the sea. Why? Because the land is cooler than the sea in the same latitudes

(2) In summer, the isotherms bend towards the Equator over the sea and towards the Poles over the land. This is because the land heats much more rapidly than the sea in similar latitudes. At this season the interiors of the continents are warmer than the coastal regions.

(3) Note the effect of ocean currents on temperatures. The North Atlantic drift, as we have seen, raises the temperature of North-West Europe. The cold Peru current, flowing northward along the west coast of Chile and Southern Peru, reduces the temperatures of these regions.

ISOBARS, CYCLONES, AND ANTICYCLONES

Just as isotherms are drawn on maps joining places of equal temperature, so *isobars* (*baros* = weight, pressure) are drawn joining equal places of atmospheric pressures. When the pressure gradient between two sets of isobars is steep, i.e. where the isobars are close together, then the winds blow with great force from the direction of the higher to the lower isobar.

FIG. 32. Note the northward bend of the January isotherm 32°F . In the southern hemisphere the 70°F . (summer) isotherm bends polewards over the land, but towards the Equator over the sea.

FIG. 33. Note how the July isotherm, 60°F ., in the northern hemisphere bends towards the North Pole. In the southern hemisphere, where it is winter, this isotherm bends north over the sea, but south over the land.

In addition to the permanent and semi-permanent world pressure systems, there are less permanent and smaller low- and high-pressure systems. These are known as cyclones and anticyclones. Such systems have a great effect on British weather, as we know from reading the Daily Weather Reports in the papers, or from hearing them broadcast.

A *cyclone* (depression) is a portion of the atmosphere in which the pressure is lowest in the centre.

FIG. 34. Direction of Winds in a Cyclone (Northern Hemisphere).

The winds blow inwards in the opposite direction to the hands of a clock. As will be seen by Fig. 34, the winds blow from the south or south-west in the front of the cyclone, and from the north or north-west in its rear. When a cyclone is approaching the barometer falls because of the low pressure, but the thermometer rises on account of the warm south or south-west winds in the front of the system. The rising moisture-laden air of such a cyclone causes rain which is

especially heavy in the centre of the depression. If, after a day or night of storm and rain, the barometer rises and the thermometer falls, we know that the cyclone is passing, for (a) the pressure is now increasing, and (b) the cold north or north-east winds in the back of the depression cause the temperature to become lower.

[In the Southern Hemisphere cyclonic winds blow in a clockwise direction in accordance with Ferrel's Law.]

A *Secondary* often occurs on the edge of a big depression, moving round it in an anti-clockwise direction. Such secondaries are also low-pressure areas. They are much smaller in extent than cyclones, but like them are usually accompanied by stormy weather.

A cyclone in temperate regions is generally several hundreds or even thousands of miles across. But in tropical regions there are small depressions (usually called Tropical Cyclones) which may measure only 50 or 100 miles across. As the pressure gradients are steep, the winds are exceptionally strong, and the resulting storms often do great damage. In the West Indies such storms are called

hurricanes, in the South-East United States they are called *tornadoes*, and in the West Pacific and China Seas *typhoons*, while the whirling dust-laden storms of the Sahara, of similar type, are termed *simooms*.

An *anticyclone* is a portion of the atmosphere in which the pressure is highest in the centre. The winds, which are usually light, blow spirally outwards (in the Northern Hemisphere) in the same direction as the hands of a clock (see Fig. 35). As the air is warmed in descending it tends to gather moisture rather than deposit it, and so the weather associated with anticyclones is usually fine and dry. As anticyclones tend to remain stationary, until displaced by cyclones, the fine weather experienced during such periods usually lasts for a considerable time. In summer the days are warm and the skies clear with little cloud. In the British Isles, during winter, the days during a spell of anticyclonic weather are cold and bright, the nights frosty and starlit. In low-lying

FIG. 35. Directions of Winds in an Anticyclone (Northern Hemisphere).

regions, however, the cold heavy air becomes laden with moisture from the damp ground and thus fogs tend to form which, owing to the absence of strong winds, often last for several days.

THE POLAR FRONT

Cyclones (depressions) tend to develop when air currents of widely different character are brought into close contact. Such is the case when cold polar air moving outward from the Arctic meets warm air from the direction of the tropics. Deflection due to the earth's rotation causes the two masses to flow alongside each other, but in *opposite directions*. The line of contact between them is termed the *polar front* (Fig. 36 a).

As will be seen by Fig. 36 b, a portion of warm air pushes its way into the cold air. This warm sector causes a small bulge (*B*) in the polar front, and this marks the beginning of a depression. The warm air moves forward and rises over the cold air to form a *warm front*. Meanwhile the cold heavy air, swirling round the increasing

bulge, pushes its way into the rear of the warm sector to form a *cold front*. As the cold front travels more rapidly than the warm

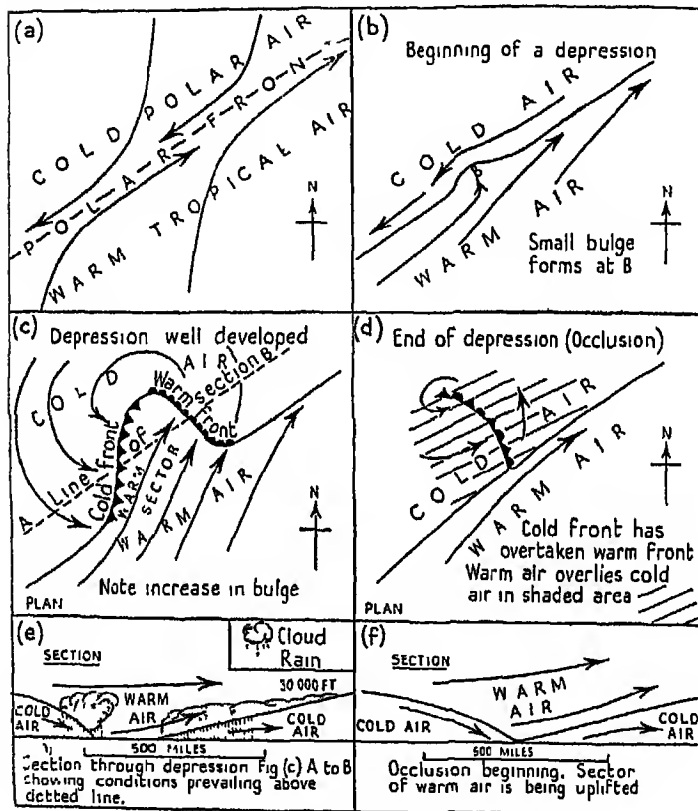

FIG. 36. The Polar Front.

front it eventually overtakes it, and the warm sector is lifted up completely from the surface. When this occurs an *occlusion* (Latin *occludere* = to close up), or closing up of the fronts takes place (see Fig. 36 d and f).

LOCAL WINDS

In different parts of the world local winds, due to a variety of causes, often have a considerable effect on climatic conditions, notably on temperature. One of the best known of such winds is the *föhn* of the Alps, a warm dry wind which blows chiefly in the valleys to the north of the main chains, especially in those of the upper Rhine, the Reuss, and the upper Aar. As currents of air ascend the mountains they pass into an area of lower pressure with the result that they expand, and being cooled deposit most of their moisture as rain or snow on the windward side of the ranges. The dry air passes over the mountain crests and on descending the leeward side is heated by compression: temperatures rise quickly and the snow melts with great rapidity. In spring the *föhn* sweeps the snow from the alpine pastures, making them available for cattle and goats sooner than would otherwise be the case; in summer it hastens the ripening of the grain, and in autumn of the grapes. The *chinook*, a similar hot drying wind, descends from the Rockies to the valleys and plains lying to the east. It turns the standing grass into hay, and in winter, by keeping the grazing grounds near the foothills relatively free from snow, enables stock to be grazed out of doors, whereas farther east on the snow-clad prairies they must be housed at this season.

The *harmattan* is a very dry and dust-laden east or north-east wind which, especially from October to February, blows from the Sahara to the Sudan. Sometimes in January and February its effect is felt along the coast of the Gulf of Guinea, where, owing to its dryness, it provides welcome relief from the usual steamy heat and is known as 'the doctor'. The *sirocco*, a hot dry south wind blowing from the Sahara to the Mediterranean, is most unpleasant. Men and animals both suffer, and often its scorching breath does great injury to vegetation and crops. In Egypt this wind is called the *khamisin*. The *mistral* and the *bora* are cold north winter winds. The former sweeps down the Rhone valley and across the Mediterranean coast from the mouth of the Ebro to Genoa. In the lower Rhone valley the peasants protect their gardens from this violent wind by planting thick cypress hedges, and build their houses so that the windows and doors face south-east. The Dalmatian coast of the Adriatic suffers in a similar way from the *bora*, which is drawn southward towards the low-pressure area over the sea.

CLIMATIC TYPES

A. TROPICAL LANDS.

1. The *Equatorial Type* has heavy rain throughout the year, and uniformly high temperatures.
2. The *Summer Rain Type* is found on both sides of the Equatorial Wet Belt. It has marked wet ('Summer') and dry seasons, and temperatures are high.
3. The *Monsoon Type* is similar to the Summer Rain Type. Heavy rains fall during the summer monsoon, but the cool season, and the hot season preceding the monsoon rains, are dry.
4. The *High Plateau Type* is a modification of the Equatorial Type due to altitude. Temperatures, though lower, are uniform, and the rainfall is less than in the lowlands.
5. The *Hot Desert Type*, as its name implies, receives little rain. It is found in the High-Pressure Belts around the Tropics of Cancer and Capricorn, where the Trade Winds blowing towards the Low-Pressure Region about the Equator tend to absorb rather than deposit moisture.

B. WARM TEMPERATE LANDS.

1. The *Warm Eastern Margins* of the continents have hot rainy summers and dry cold winters.
2. The *Mediterranean Type* is found on the western margins of the continents, between latitudes 30° and 40° . The summers are hot, dry, and sunny, the winters mild and showery.
3. The *Interior Lowlands* have a continental climate, with hot summers, cool winters, and low rainfall.
4. The *Plateau Type* of climate resembles that of the Interior Lowlands (B. 3), except that the summers are not quite so hot and the winters somewhat cooler.

C. COOL TEMPERATE LANDS.

1. The *Eastern Margins* of the Cool Temperate Lands have warm summers, cold winters, and rain throughout the year, but most in summer.
2. The *Interior Lowlands* have a continental climate with hot summers, cold winters, and a light rainfall with a spring maximum.

3. The *Western Margins* of the continents have an insular climate. The summers are cool, the winters mild, and rain falls at all seasons.
4. The *Mountain Type*. Temperatures are reduced through elevation. The windward slopes have a heavy rainfall, but the sheltered valleys and intermont plateaus are dry. There is a marked *Rain Shadow* on the leeward slopes of the mountains.

D. COLD LANDS.

1. The *Tundra* have an extreme climate. The winters are very cold, the summers are cool (slightly under 50° F.), and the rainfall scanty (under 8 inches). The ground is permanently frozen a few feet below the surface.
2. The *Cold Deserts* are always covered with ice and snow.

EXERCISES

1. Describe how the earth's surface is heated. Give a diagram.
2. Write notes on relief rains, the formation of dew, rain shadow, isobars, and relative humidity.
3. What is an isotherm? Trace and account for the course of one isotherm round the world.
4. Under the headings given, summarize the characteristic features of (a) a cyclone, and (b) an anticyclone. (i) Pressure, (ii) State of barometer, (iii) Direction of winds, (iv) Typical weather.
5. Describe and account for the weather sequence which you would expect in Central Scotland after it had been broadcast that a deep depression off western Ireland was moving rapidly eastward.
6. The centre of a cyclone moves over Donegal, Glasgow, and Inverness. (a) Draw a map to show the weather conditions when the centre is over Donegal. (b) Describe the direction of the winds and the kind of weather you would expect when the depression is travelling over (i) Glasgow, and (ii) Inverness. (Note. Make a tracing of your map (a) above, on transparent paper. Before answering (b) place your tracing so that the centre of the depression is (i) over Glasgow, and (ii) over Inverness.)
7. What are the characteristic features and local importance of the following winds: (a) Föhn, (b) Mistral, (c) Harmattan, (d) Simooms, and (e) Typhoons?
8. How do you account for the following: (a) in mountainous regions the temperature is sometimes lower in the valleys than at greater heights; (b) in the British Isles in winter there is sometimes thick fog for several days in the valleys, while during the daytime the hills are frequently bathed in sunlight?

CHAPTER VII

MAJOR NATURAL REGIONS OF THE WORLD

WE may divide the world into a number of major natural regions whose physical features, rock structure, soils, climate, and resultant products and human activities are similar over large areas. Of all the factors affecting the natural vegetation in such regions, climate is the chief, and of the climatic factors, temperature and rainfall are the most important. The vegetation depends not only on the total annual rainfall, but on its relation to temperature, and on its distribution. In short, evaporation and the seasonal distribution of the rainfall are the real test. In high latitudes evaporation is less than in low latitudes, and hence less rainfall is needed to keep the subsoil moist than in tropical regions.

As a rule no sharp contrast can be drawn between adjacent natural regions: the transition from one to the other is gradual. Plant and animal life is adapted to its surroundings. Man, too, has adjusted himself to his environment, though in many cases the appearance and habits of people living in similar natural regions differ greatly. In some, Man counts for little more than the animals: in others, such as Europe and China, he has profoundly altered the surface features. Natural regions would, of course, exist whether Man were there or not, but no study of them can be considered complete without some knowledge of the activities of their human inhabitants.

An examination of the effect of climate on human life shows that very high and very low temperatures both prevent the fullest attainment of mental and physical powers, and even in less extreme regions uniformity of temperature exercises an adverse effect on development. High humidity, combined with high temperature, produces an enervating climate. Man's progress has been greatest in cool temperate lands where the climate is cool enough to invigorate, but not cold enough at any season to retard economic life.

We may divide the major Natural Regions of the world into four groups. The following regions in each group are numbered to correspond with the coloured map at the end of this book.

3 HIGH PLATEAU AND COLD DESERT

(Above) A Tibetan plateau (see p 71), isolated between great fold ranges. There is rough pasture for yaks and sheep. The building is constructed of sun dried bricks and stone. But many parts of Tibet are scarcely less hospitable than the Antarctic region (below), where the climate of Erebus

4 SAVANNAS AND TROPICAL FORESTS

On the savannas (above) the trees grow singly or in clumps. The uniform colouring of the lion blends equally well with the brown grasses and the rocks and sands of the desert into which the savannas merge. The tropical monsoon forests of South-East Asia (below) are more open than the equatorial forests. Dyaks, the aboriginal inhabitants of Borneo, whose villages

A. TROPICAL LANDS.

1. Equatorial Type.
2. Summer Rain or Savanna Type.
3. Tropical Monsoon Type.
4. High Plateau Type.
5. Hot Desert or Sahara Type.

B. WARM TEMPERATE LANDS.

1. Warm Eastern Margins or China Type.
2. Mediterranean Type.
3. Interior Lowlands (Warm) Type.
4. Iran Plateau Type.
5. High Plateau Type.

C. COOL TEMPERATE LANDS.

1. Eastern Margins of Cool Temperate Lands.
2. Interior Lowlands. Cool Forest Type.
3. Interior Lowlands. Cool Grassland Type.
4. Western Margins of Cool Temperate Lands.
5. Mountain Type.

D. COLD LANDS.

1. Tundra Type.
2. Cold Desert Type.

THE TROPICAL LANDS

A. 1. **The Equatorial Type.** In the equatorial belt the sun's altitude is never less than $66\frac{1}{2}^{\circ}$; its rays shine down more or less directly throughout the year; and temperatures are uniformly high. There are convectional rains at all seasons, but they are especially heavy at the equinoxes (Fig. 37). Most rain falls in thunder showers that occur every afternoon, i.e. in the hottest part of the day. The greater part of the Amazon and Congo basins is clad with tropical forest. From a dense undergrowth trees spring up in tiers. The struggle is not for moisture, but for light and air, and so close together are the forest giants that they are unbranched except at the top. Trees include logwood, mahogany, coco-nut and oil palms.

Malaya and the East Indies form a subdivision of this region,

FIG. 42. (B. 1.)

Natural Regions of the World. Monthly temperatures and rainfall.

though, owing to their maritime position, their forests are less dense than those of the Amazon.

In the more open tropical forests animals like the tigers of the monsoon lands and the leopards and the elephants of Asia and Africa are found. In the denser areas, owing to difficulty of movement, many animals, such as the gorillas of West Africa, are tree-dwellers; while others, like the crocodiles and rhinoceroses of the Old World, live in or by the rivers.

A. 2. The Summer Rain or Savanna Type. The tropical grasslands, or savannas, are found on both sides of the equatorial forests. Temperatures are uniformly high, rain falls during the summer months, but the cool season is dry (Fig. 38). Soon after the rains begin the grass commences to grow rapidly, springing up in clumps, usually from 6 to 12 feet high. Trees, which stand singly or in groups, are of the drought-resisting variety, such as acacias, baobabs, and eucalypts (Australia), for they must be able to withstand the dry season. In Africa the northern savannas are known as the *Sudan*. The savannas of the Orinoco basin are termed *llanos*, and those of the Brazilian Highlands, *campos*. Savannas are also found in the drier parts of India, in the higher regions of the East Indies, and in the north and east of Australia. Among the chief crops are cotton, sugar-cane, maize, coffee (Brazil), and, in drier areas, millet and ground-nuts.

The African savannas are the home of such ungulates, or hoofed animals, as antelopes, giraffes, buffaloes, zebras, and elephants; and carnivores like lions, hyenas, and leopards. The ostrich, too, is found in this region, while in Australia the emu is a savanna bird. Stock-rearing is important.

A. 3. The Tropical Monsoon Type is very well marked in India and Pakistan, and is also found in Indo-China, South China, and Northern Australia. The monsoons are due to the development of low-pressure areas over the land during summer, when inflowing winds bring heavy rains; and to high-pressure areas over it in winter, which is a dry season, as winds blow from land to sea (Fig. 39). In areas where the rainfall is over 80 inches the dense forests are somewhat similar to those of equatorial regions. The typical, and more open, monsoon forest, with teak, baobabs, and other deciduous trees which shed their leaves in the dry season, is found in regions where the annual rainfall is between 40 and 80 inches. 'Such forests

are perhaps less rich in natural resources than the hot rain forests, but they are healthier and more easily cultivated and more favourable to human settlement.¹ In the wetter regions the crops include rice, tea, and jute. In areas where the rainy season lasts from six to seven months cotton and sugar-cane can be cultivated. In drier districts millet is the chief cereal crop.

Among the monsoon animals are elephants, lions, tigers, leopards, and various types of monkeys.

A. 4. The High Plateau Type. In this modification of the equatorial type, heat is tempered by altitude. Temperatures are remarkably uniform though much lower than those of the lowlands. The rainfall is less than in the lowland areas and tends to be seasonal (Fig. 40). The best example of this type is found on the Plateaus of Ecuador and Colombia, in South America, where the climate has been described, somewhat optimistically, as 'perpetual spring'. Crops such as barley and wheat, grown for local needs, ripen with difficulty. Stock-rearing is the chief occupation. On the East African Plateau—a tropical plateau of moderate elevation—savannas are found at lower elevations, while temperate crops can be grown in higher areas.

A. 5. The Hot Desert or Sahara Type. From the high-pressure belts, about 30° N. and 30° S., the trade winds blow towards the low-pressure belt round the Equator. As they are flowing from cooler to warmer regions they become warmer as they proceed, and tend to absorb rather than deposit moisture. Thus they are dry winds (Fig. 41). For this reason, a desert belt is found around the tropics on the *western sides* of the continents. In North Africa, owing to the presence of a great land mass to the east, the Sahara extends right across the continent, and the desert belt of which it forms a part is continued into Arabia, and thence across Central Asia. In the west of the United States the desert and arid area about the Tropic of Cancer includes the Colorado, Mohave, and Gila Deserts. The chief deserts of the Southern Hemisphere are the Atacama of South America, the Kalahari of South Africa, and the Great Australian Desert.

Desert soil only requires irrigation to make it fertile. Sometimes the water is obtained from underground supplies, as in the typical oasis. In other cases it is got from rivers like the Nile, the Indus, or the Colorado. The presence of minerals has induced man to settle

¹ *A Junior Plant Geography*, M. E. Hardy (Clarendon Press).

in such regions as (i) Western Australia, e.g. Kalgoorlie, for gold; (ii) the Western Mountain States of the United States, for various minerals; and (iii) the Atacama Desert, to obtain nitrates and copper. In spite of the building of railways across, or to the margins of desert areas, and of motor transport, the camel is still an important beast of burden, for it can carry heavy loads. Its padded feet, specially adapted to traversing sandy areas, prevent it from sinking into the sand; its hump enables it to store up reserve supplies of food, and the cellular apparatus in its stomach, of water, while it can close its nostrils during sand-storms. In Africa the lands bordering the desert and the savannas are the home of the lion, whose tawny coat enables it to blend with the sands and the parched savanna scrub and grasses.

WARM TEMPERATE LANDS

B. 1. The Warm Eastern Margins or China Type. The chief climatic characteristics of this region are hot rainy summers and dry cold winters (Fig. 42). Central and Northern China are typical areas, but others belonging to it are Japan and the South-East United States in the Northern Hemisphere; Natal and the east of the Cape Province in South Africa; New South Wales, Southern Queensland, and South-East Brazil in the Southern Hemisphere. It should, however, be noted that (a) Japan and North and Central China receive monsoon rains, and (b) the eastern marginal lands of the Southern Hemisphere have a milder climate than their northern counterparts. High summer temperatures and heavy rains favour evergreen forests, with walnut trees and shrubs like laurel and camellia. Cultivated plants include rice, cane sugar, cotton, tobacco, coffee, and tea. The Sino-Japanese—the Temperate Monsoon—Region is one of the most densely peopled areas in the world.

B. 2. The Mediterranean Type reaches its greatest extension around the Mediterranean Sea. Outside this region it is limited to *west coast lands between latitudes 32° and 38°*, such as Central California, Central Chile, the south-west of South Africa, and South-West Australia. During winter the Mediterranean lands lie in the path of the on-shore, rain-bringing Westerlies; in summer they are in the track of the trades, which blow off shore, or parallel to the coast (Fig. 43). The vegetation is adapted to withstand the summer drought, and both trees and shrubs are mainly evergreens.

FIG. 43. (B. 2.)

FIG. 44. (B. 3.)

FIG. 45. (B. 5.)

FIG. 46. (C. 1.)

FIG. 47. (C. 3.)

FIG. 48. (C. 4.)

Natural Regions of the World. Monthly temperatures and rainfall.

Deciduous trees are found only in better-watered areas, and there is an absence of pasture for cattle. Cereals, such as wheat and barley; the olive and the vine; and warm temperate and citrus fruits (oranges, lemons, and grapefruits), are widely cultivated.

B. 3. The Interior Lowlands (Warm) Type. This region is also known as the *Turan Type*, as it reaches its greatest extension in the lowland of Turan, which stretches from the Caspian eastward towards the Pamirs, and from the northern edge of the Plateau of Iran northward, beyond the Sea of Aral, to the Kirghiz steppes. The climate is continental, with hot summers, cool winters, and a low rainfall (Fig. 44). In the southern part of the United States the area extends from the Rockies eastward to 100° W. In South America the west of the pampas, and in Australia much of the Murray basin, may be included in this region.

The natural vegetation is grassland as, except in favoured districts, there is insufficient rainfall for trees. In Turan nomadic herdsmen pasture their flocks on the steppes in spring, but migrate to the lower slopes of the mountains in summer. Stock-rearing is important, especially in the 'newer' countries. Where the annual rainfall exceeds 12 inches, wheat and other cereals can be grown: specially favoured areas in this respect are the pampas and the Murray basin. Fruit is cultivated on irrigated lands, like the Riverina district in the Murray basin, and that round Mendoza and other centres lying amidst the Andean foothills. Much fruit is also grown in Turan, where cotton, too, is an important crop.

B. 4. The Iran Plateau Type. Plateaus of moderate elevation, like the Plateaus of Iran and Asia Minor, and the Tarim Basin, have a climate resembling that of the Interior Lowlands, except that the summers are not quite so hot, and the winters are cooler. Outside Asia we may include in this type the plateaus lying between the main chain of the Rockies and the Sierra Nevada; parts of the Mexican Plateau, and the Veld of South Africa. The natural vegetation is grassland. Stock-rearing is the chief occupation.

B. 5. The High Plateau or Tibet Type. Owing to its great elevation (12,000 to 14,000 feet) and to the isolating effect of mountain barriers, Tibet has an extreme climate with very cold winters. Some agriculture is carried on in sheltered valleys, but the people are mainly pastoral, breeding sheep, goats, and yaks for food, wool, and transport purposes. The Plateau of Bolivia, as it lies nearer the

Equator and not so far from the ocean as Tibet, has a less extreme climate (Fig. 45). Hardy cereals and potatoes are the chief crops. The dwarf camels, known as alpacas, vicuñas, and llamas, are raised for meat and wool. The sure-footed llama, which can carry loads of 100 pounds, and can go for four or five days with little food and no water, is the chief transport animal.

THE COOL TEMPERATE LANDS

C. 1. The Eastern Margins of the Cool Temperate Lands have a more extreme climate than the western ones. In the Northern Hemisphere they include Eastern Canada, Manchuria, and Amuria, Northern China, Northern Japan, Sakhalin and Korea. In the Southern Hemisphere we may include Patagonia in this region. The prevailing winds are off-shore. Thus they have a moderate to light rainfall and are hot in summer and cold in winter (Fig. 46). Though cyclonic storms bring rain, the annual amount is less than in the western marginal lands. In winter rivers are frozen, and the more northerly ports ice-bound for some months. The natural vegetation consists mainly of coniferous and deciduous forests. In cleared areas mixed, dairy, and fruit farming are important.

The **Cool Temperate Interior Lowlands** are found in Canada and Siberia, whence they extend into European Russia. They have a continental climate. The rainfall varies from moderate to light, diminishing towards the west in Siberia and the east in Canada. Most rain falls in summer (Fig. 47). In winter the snow helps to protect the ground, and in spring it softens it and adds to its moisture content. We may divide these Interior Lowlands into the **Cool Forests** and the **Cool Temperate Grasslands**.

C. 2. The Cool Forests form a wooded girdle round the land mass of the Northern Hemisphere. Though the rainfall is low, yet, thanks to the small evaporation, it is sufficient to keep the subsoil moist enough for pines and similar evergreen trees. Forests cannot grow where the summer temperature is less than 50° F., and thus the dividing line between the woodland belt and the tundra to the north is determined by summer temperature. Lumbering, mining, and trapping are important. In Russia, despite great strides that have been made in recent years, the felling of timber has not yet attained an importance comparable with that of Canada and Sweden.

C. 3. The Cool Temperate Grasslands. Though in the steppes

of Russia and the prairies of Canada the moisture is insufficient for trees, it is ample for grasses. The drier parts are stock-rearing areas, but the regions with a somewhat greater rainfall are devoted to the large-scale cultivation of cereals. In Canada the cultivated zone is beginning to invade the forest belt, and the efforts of the agricultural scientists 'are directed to the breeding of varieties of wheat which will ripen in the short, intense summers with their long days'.¹ Rye, oats, and barley are the crops best suited to the marginal region.

C. 4. The Western Margins of the Cool Temperate Lands, exposed to the on-shore westerly winds, have an insular climate, with cool summers, mild winters, and rain throughout the year, especially in autumn and winter (Fig. 48). British Columbia, North-West Europe, Southern Chile, Tasmania, and most of New Zealand lie within this region. The natural vegetation consists of coniferous and deciduous forests and grasslands. Much land has been cleared for cultivation. Temperate cereals and fruits, roots like potatoes and sugar-beet are widely cultivated. Dairying and stock-rearing are important.

C. 5. The Mountain Type. In cool temperate latitudes there are extensive lofty mountain belts in the interiors of Asia and North America. In the former continent they comprise the North-East Highlands: in the latter they form the northern portion of the Western Mountain System. The rainfall is heaviest on the northern slopes in Siberia and on the western slopes in Canada. The leeward sides of the mountains and the interior valleys are dry. Lumbering and minings are the chief occupations.

THE COLD LANDS

D. 1. The Tundra, or polar lowlands, are found in the extreme north of Eurasia and North America. In the latter continent they are aptly known as the Barren Lands. For two-thirds of the year the tundra are buried in snow, and rivers and lakes are frozen to a great depth. In May temperatures begin to rise and the greenish gloomy night is succeeded by continuous daylight, during which time the sun does not sink below the horizon for several months. The melting snow exposes the mosses, lichens, and low berry-bearing bushes, and soon the ground is covered with innumerable flowers. Birds and animals, too, respond to the miracle of spring.

¹ *Handbook of Canada.*

Enormous flocks of snow-geese, eider ducks, cranes, and ptarmigan darken the air as they fly northward to nest; and herds of reindeer leave their winter quarters on the margins of the forest and travel towards the ocean. In the Old World the reindeer are domesticated: in North America they are still wild, though domesticated herds have been introduced into Alaska and Northern Canada. Towards the end of August the thermometer begins to fall, and in less than a month winter again reigns over these vast expanses, almost unexplored and unmapped by Man.

D. 2. **The Cold Deserts** stretching round the Poles are always covered with ice and snow. The outstanding climatic features are low temperatures and the length of the summer days and winter nights. The continent of Antarctica, around the South Pole, consists for the most part of a high plateau buried beneath an Ice Sheet of unknown thickness. The pack-ice often stretches for hundreds of miles from the coast, though the extent varies from year to year. Greenland, and the higher parts of the Arctic archipelago, are also of this type.

EXERCISES

1. What do you mean by a Natural Region? What are the chief factors affecting the development of such regions? In what region, or regions, has Man's progress been greatest, and why?
2. Into what major Natural Regions would you divide the Temperate Zone? Describe the climate and natural vegetation of *one* of these regions and show how the latter is adapted to climatic conditions.
3. Describe the climatic conditions and natural vegetation of the Equatorial Forest Belt. What are the chief differences between this region and the Monsoon Forests, and how do these differences affect the cultivation of typical products?
4. Draw a map of *one* continent and divide it into major Natural Regions. Select *one* region and describe its climate, vegetation, and animals.
5. In what parts of the world are the following animals used for transport and allied purposes: the reindeer, camel, yak, llama, and elephant? Show how any *three* of these animals are adapted to their environment, and state the kind of work each performs.

CHAPTER VIII

THE PEOPLES OF THE WORLD

The Primary Races. Mankind is usually divided into three *primary* races: (1) the *Caucasian*, popularly termed the White Race; (2) the *Mongolian*, or Yellow Race; (3) the *Negro*, or Black Race.

The map (Fig. 49) shows that the Caucasians are found mainly in Europe, North Africa, and South-West Asia. The rest of Asia is occupied chiefly by Mongolian peoples. The Americas are the home of the 'Red' Indians.¹ Most of the negroes live in Africa, south of the Sahara, but there are a large number in the South-East of the United States and the West Indies, as well as in some parts of Tropical South America. The majority are the descendants of freed slaves brought from Africa to work in the plantations.

There is much intermixture of race, especially in marginal areas. The primary divisions are based on the colour of the skin, which is due to variable pigments. But colour alone is not an entirely reliable guide. Most of the people of Europe are Caucasians, but whereas the Norwegian has a fair skin and fair hair, and is usually blue-eyed, the Italian has an olive skin, dark hair, and dark eyes. Negroes vary from a light chocolate hue to almost coal black. Both the Japanese and the Bushmen of the Kalahari are yellow in colour, but they belong to different races.

Actually the texture of the hair provides a surer test of race. Hence terms based on the hair should be linked with the more popular names based on colour. The hair of the Caucasian is oval in cross-section, and is wavy. That of the Mongolian is round in cross-section, and is long and straight, hanging loose like a piece of string. The Negroes have woolly hair arranged in small interlocked spirals, and if a section of such a hair were examined under a microscope it would be seen that it was flattened in cross-section.

There are, of course, other physical characteristics associated with the different races. Mongolian people, such as the Chinese and Japanese, have broad flat faces with high cheek-bones, almond-shaped eyes, and are of rather short stature.

¹ The 'Red' Indians of America are now regarded by most authorities as a branch of the Mongolian Race.

The Negroes as a rule are tall. They have thick lips and broad, flat noses. Their original home was in Africa, south of the Sahara, where the bulk of them live to-day. The Sudanese Negroes who, as their name implies, live in the Sudan, are very dark brown in colour. The Bantu Negroes, who form the majority of the inhabitants of Africa south of the Sudan, are lighter in colour than the Sudanese, and their noses are often less flat and broad. The Pygmies, who inhabit the depths of the Congo forests, do not exceed $4\frac{1}{2}$ feet in height. Though the Bushmen and Hottentots of the Kalahari Desert are yellow-skinned their hair is woolly like that of the Negroes. In the West Indies, Negroes form the bulk of the population, while in the United States there are nearly 15 million Negroes, 75 per cent. of whom live in the south-east.

The people of Malaya, the Papuans of New Guinea, and the Polynesians and Melanesians living in the islands of the South-West Pacific vary in colour from quite light brown to black. The aborigines of Australia, a primitive race now few in number, are dark-skinned and have shaggy hair.

At the dawn of history Europe seems to have been inhabited by three branches of the Caucasian Race. (i) Around the Mediterranean lived a short, slender, dark-haired, and dark-complexioned people with very long heads. They had probably come from Africa at the time when the two continents were joined by land across the Strait of Gibraltar, and from Tunis to Sicily. These folk are now known as the *Mediterranean Race*. (ii) At a later date other peoples entered Europe from Asia. They travelled westward, following the setting sun, and settled in the upland regions—the Alps, the Central Plateau of France, and the Pyrenees. These people, who had brown hair, fairly dark complexions, and round heads, were somewhat taller than the Mediterranean Race, and as they inhabited the uplands they are now called the *Alpine Race*. (iii) Most of the people who live in Northern Europe belong to the *Nordic Race*: they are tall, with fair hair, blue or grey eyes, and have long heads.

The present peoples of Europe are a mixture of these and some other stocks, but in few regions do we find pure racial strains. The Europeans have expanded overseas, where their descendants compose the greater part of the inhabitants of North America and Australia. In the South African Republic 21 per cent. of the population is of European descent, and nearly 70 per cent. are Bantus of negro

origin. There are a large number of people of European—mainly Mediterranean—stock in South and Central America, though in these regions a still greater number are of mixed European and Indian blood.

Superficial observers sometimes describe the Negro as lazy, but competent authorities say that though he may be less efficient than the European in activities that secure success in modern

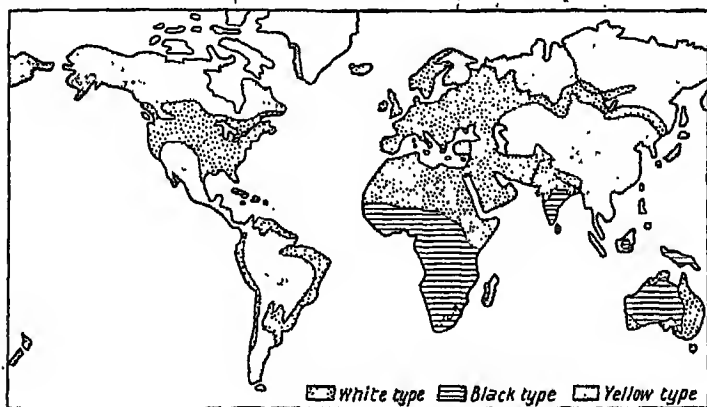

FIG. 49. Distribution of Primary Races.

life, yet in his natural environment he is a painstaking worker and delights in manual labour. Good-tempered and affectionate the Negro undoubtedly is, and blessed with a strong sense of humour.

The Mongolian is an artistic craftsman and a great organizer. In countries like China he has been one of the pioneers of those large-scale irrigation works essential to enable the land to support an enormous agricultural population.

The European, including his descendants overseas, displays a genius for large-scale co-operation. 'He is possibly no more inventive than the Chinese, but he is unrivalled in the common sense and insight with which his inventions are applied in practice and developed on a great scale. Modern industrialism is due to his instinct for co-operation—all the great instruments of its progress, such as the steam engine, electric power, the internal combustion engine, and metallurgy, require the co-operation of experts in many

branches of science, of great industrial organizers, and men of business.'¹

Simple Occupations. The racial stock from which they spring, the kind of region in which they live, and their past history all unite to form the background of a people. It is mainly in the temperate lands that Man has attained his highest development. The North Temperate Zone has been the home of all the greatest civilizations of ancient and modern times—Egyptian, Babylonian, Persian, Hindu, Chinese, Minoan (Cretan), Phoenician, Greek, Roman; and at a later date, European, which has spread throughout the temperate lands of the Americas, Africa, and Australia.

Outside these temperate regions, with their invigorating climate, Man has lagged behind. During the last four centuries contact with Europeans has played a great part in the development of native peoples, but in many parts of the world even to-day are tribes living under primitive conditions. A few, like some of those inhabiting the depths of the Amazon forests or the Australian aborigines, are mainly collectors, living on fruits, nuts, berries, and birds' eggs. Others, such as the Eskimos of the cold lands, are chiefly hunters and fishers. In some of the arid areas of Asia, and on the African savannas, live nomadic tribes who depend almost entirely on their flocks and have no settled homes. But others more advanced are agriculturists, tilling their plots of land, and living in semi-permanent villages. Some of these folk are skilled craftsmen, smelting iron and forging weapons and simple agricultural implements: others weave and some fashion pottery. All these simple occupations represent stages in Man's development, and are in essentials closely allied to more advanced occupations such as large-scale agriculture, mining, modern manufacturing, engineering; and to transport, on which all branches of modern industry depend.

Distribution of Population. Among the major geographical conditions which determine the density and distribution of population in any region are (a) *climate* (notably temperature and rainfall), which greatly influences (i) natural vegetation and crop production, and (ii) the suitability of a region, e.g. as regards healthiness, for human settlement; (b) *relief*: other things being equal, mountain areas are sparsely settled or virtually uninhabited, and people tend

¹ *Race as a Political Factor*, Professor Gregory.

to congregate in the river valleys and the lowlands, where in thinly populated countries, e.g. Canada and Australia, they are spread along the main transport routes, these being determined largely by relief; (c) *rock structure* and *mineral resources*, especially coal, which is of great importance in deciding the local density of population in any area; and (d) *available water supply*.

The most populous regions in the world are (a) the industrial areas of Europe and the United States, and (b) the monsoon lands of Asia.

The Industrial Revolution—the Machine Age—which began in Britain towards the middle of the eighteenth century, established the factory system, and from that time the great coal-fields of Britain, and those of France, Belgium, and Germany, and more recently those of Russia, became increasingly important centres of production and dense population. To-day these and other coal-mining districts in Europe, together with those in the North-East United States, are densely populated areas whose people, living in large towns and cities, are engaged chiefly in industry, trade, and commerce. Though petroleum and electricity are now challenging coal as sources of mechanical power, heavy industries, such as iron and steel, are still tied to the coalfields, or to regions readily accessible to supplies of coal and iron ore.

In the present century the use of electricity has played a great part in establishing many varied industries outside the coal-mining areas. Thus in Britain, both Greater London and the surrounding counties have in recent years become one great industrial district whose factories depend, in large measure, on electricity for their power. The inhabitants do not, however, live in such congested conditions as those in the older manufacturing areas, for outside London itself the factories are more widely spread, and adequate transport is available to convey the workers to and from their homes.

Industrial countries, like the United States and the United Kingdom, thanks to their great resources of mechanical power, are able to support populations, which are much larger and have a much higher standard of living, than would be the case if their inhabitants relied primarily on agriculture for their livelihood. In short, the prosperity of the great manufacturing nations may be said to depend on their supplies of power. And power means industrialization, and this means the growth of cities. In recent decades a steady increase in the size of most big cities has been

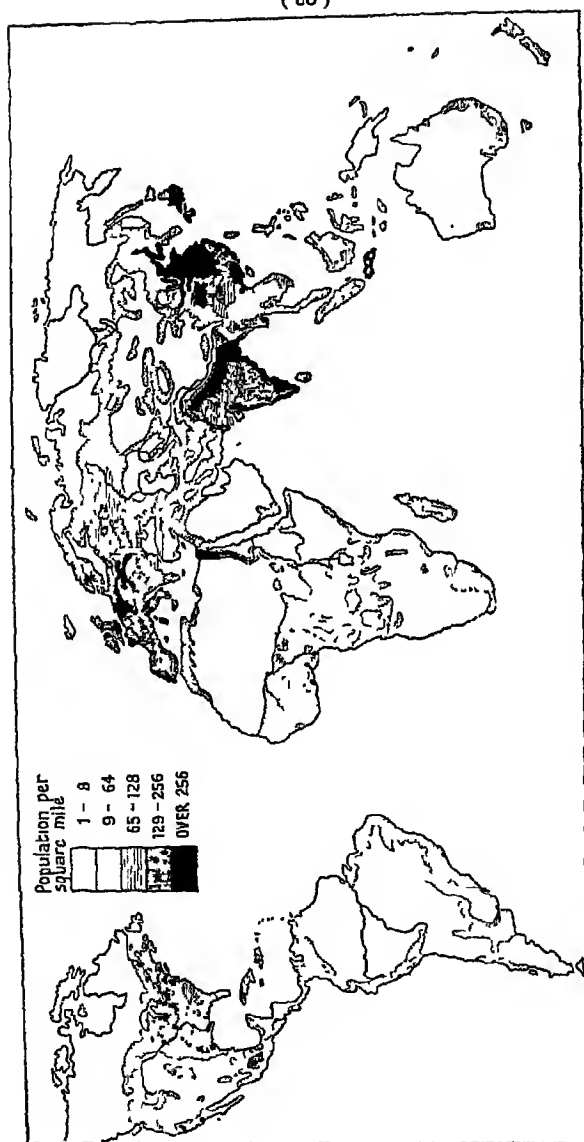

FIG. 50. The World. Density of Population.

5. CONTRASTS IN ASIA

(Above) A Hindu—descendant of the Indo-Aryans from Central Asia who invaded India about 1500 B.C. He carries the trident of Siva. (Below) A Chinese fisherman who uses a tame otter to scare fish into his net. His broad, flat face, high cheek-bones, almond-shaped eyes, and straight black hair are typical of his Mongolian race.

6. SUDANESE AND ABORIGINES

(Above) This young West African is seen on a pineapple plantation in the Guinea Republic. His very dark brown skin, woolly hair, broad nose, and wide nostrils, and his thick lips, tell us that he belongs to the Sudanese branch of the Negro Race. (Below) An Australian aborigine with shield and spear. These stone-age inhabitants of Central Australia depend mainly on hunting, for they grow no food crops and have no domesticated animals except the dog. The prevailing vegetation consists of mulga-trees and porcupine grass.

accompanied by a drift from rural to urban areas. In progressive countries the decline in the rural population is due partly to the mechanization of agriculture, since this enables fewer people to produce more food from any given area.

The Asiatic monsoon lands with their very wet, very hot summers and drier cool seasons are extraordinarily productive, and owing to their great fertility have become one of the most densely inhabited regions on earth. In parts of China the number of people over considerable areas exceeds 2,000 to the square mile, while the greater part of this vast country is intensely cultivated and thickly inhabited.

Parts of the tropical forests of South-East Asia are thickly populated, for most of this region consists of islands and peninsulas that are easily penetrated from the sea. Moreover, the sea has a moderating effect on their climate, making them healthy when compared with a region such as the Amazon. This area was developed by white peoples, mainly British and Dutch. In Malaya there are over 150 people to the square mile; in Java the number exceeds 700; and over the whole area, if we exclude these two regions, densities are roughly between 30 and 40 to the square mile. A further study shows that the larger (and, therefore, the less accessible) the island, the less dense is the population.

For generations the lands round the Mediterranean Sea have been comparatively densely peopled, and in those parts of the world with a similar climate settlement is steadily increasing. In most 'Mediterranean' regions man is mainly a farmer; in Europe and North Africa, owing to the mountainous nature of the land and the necessity for irrigation, farms are small and every foot of suitable land is intensely cultivated.

The temperate grasslands, such as the prairies, pampas, and steppes, are not thickly peopled. The construction of trans-continental railways has, however, played a great part in their development, and in each area the most populous belts are those lying within reach of the line. Nothing that man can do for the opening up of a country is more effective than the building of railways.

The extent of the arid area in Australia has limited settlement chiefly to the more favourable climatic areas along the south-east and east coasts. The development of irrigation is, however, enabling fresh areas to be settled, especially in the Murray Valley.

The Population Map of the world (Fig. 50) shows that the cold

deserts and tundra, the coniferous forests, and the hot deserts and arid lands are almost uninhabited. Here and there in the latter regions, mining settlements, as, for example, the gold-fields of Western Australia, form populated patches amidst sandy wastes; while irrigated areas like the narrow Nile valley, crossing the east of the Sahara, support a large number of people, especially in Egypt where in the valley itself and the Nile delta is found one of the densest populations in the world.

From the point of view of population the vast tropical forests of the Amazon are one of the world's desert areas, for in spite of their wonderful luxuriance, these regions have less than one person to the square mile. In these ever-hot, ever-wet *selvas* there is a continual fight between Man and Nature; the forest soon reconquers any clearing, and it is only by constant effort that Man can hold his own.

On the other hand, the forests of the Congo, with eleven persons to the square mile, are somewhat less sparsely populated. This is largely due to their greater elevation, which causes the forests to be less dense and at the same time more healthy than those of the Amazon. The forests along the coastal belt of West Africa are even more thickly peopled. As in South-East Asia, this region owed much of its development to Europeans. In Southern Nigeria there are over 150 persons to the square mile; in Ghana there are more than 50, and in Sierra Leone the number exceeds 70 persons to the square mile.

EXERCISES

1. Name the three primary races into which mankind is usually divided. In the case of each write short notes on their (a) colour and general appearance, including stature, facial appearance, and texture of the hair; and (b) general distribution throughout the world.

2. Confining your answer to the Northern Hemisphere, choose *one* densely peopled region and *one* sparsely peopled region and account for the denseness or sparseness of each.

3. Throughout most of the Amazon Basin there is less than 1 person to the square mile; in the Congo there are 11 persons to the square mile; and in Java there are over 700 persons to the square mile. Each of these areas lies in the Equatorial Forest Belt. How do you account for the differences in the density of population?

4. Give some account of the major geographical conditions which have to be considered when attempting to explain the density and distribution of population in any country. Illustrate your answer with specific examples.

CHAPTER IX

MAPS

Scales, &c. Much may be learned from a study of maps, and to those who can read them they are fascinating things. When a piece of country is represented on a map the drawing is, of course, very much smaller than the actual area. But it is proportionate in every part to the district or region it represents. In short, it is drawn to scale. *A Scale shows the PROPORTION that the distance between any two points on a MAP bears to the distance between the same two points on the GROUND.*

In atlases maps are rarely drawn to the same scale, because while the countries represented differ greatly in size, the pages of the atlas are all alike. On pages of the same size the map-maker represents Great Britain, about 600 miles in length, and North America, more than six times as long. Maps, such as these, on which 1 inch represents a distance of many miles on the ground, are called Small-scale Maps.

Most ordnance maps of the British Isles are drawn on a scale of a $\frac{1}{2}$ -inch, $\frac{1}{4}$ -inch, 1-inch, or 6 inches to 1 mile. Maps, like these, which represents a small area with a large amount of detail are known as Large-scale Maps. As there are 63,360 inches in 1 mile, a map on which 1 inch represents 1 mile on the ground is said to be drawn to a scale of 1 : 63,360. This scale is also written thus : $\frac{1}{63,360}$, and this fraction is called the *Representative Fraction* (R.F.). Note that the numerator of the Representative Fraction must always be 1.

Example. The scale of a map is 6 inches to a mile. What is the Representative Fraction ?

$$\text{R.F.} = \frac{\text{map}}{\text{ground}} = \frac{6 \text{ ins.}}{63,360 \text{ ins.}} = \frac{1}{10,560}$$

Representation of Heights. On maps heights are represented in various ways. On many maps they are shown by using colours. On others by shading. The highest lands are represented by the darkest shading, the next in height by less dark shading, and so on. On

some large-scale maps hachures, or short shading lines, are used to denote relief. Such lines are drawn directly down the slopes, and as the steepness of the latter increases so, too, is the number of hachures increased. Thus the shading on a hachured map shows how the slope varies from place to place. On ordnance maps the

FIG. 51.

heights of certain points are marked thus, 480. Such heights are known as spot heights.

If we examine a 1-inch ordnance map we shall notice clusters of thin lines forming figures of irregular shapes, each line being marked with a number. These lines are *contour lines which have been drawn to join places of equal height above sea-level*. For example, one line may be marked 400 and the next 300. This indicates that the land on these lines is 400 and 300 feet respectively above sea-level; and that the land between them varies in height between 400 and 300 feet. If the lines are close together the slope is steep; lines farther apart indicate a more gradual slope. The vertical height of one contour above another is known as the *Vertical Interval (V.I.)*. On most British ordnance maps the Vertical Interval is either 50 or 100 feet.

Examine Fig. 51 showing three river valleys. Note that each valley is V-shaped. Note also the point where each stream cuts across the contour lines. You will see that at each of these points the contours are V-shaped, and that the arrows formed by the contour

FIG. 52.

lines and the streams point up-stream towards the source. Note that the spur, projecting between the two main valleys, is U-shaped. On an ordnance map distinguish between the spurs and the valleys which follow alternately. Note also the ring contours which denote hills (Fig. 52).

The slope between any two points on a map is said to be *concave* when one point is visible from the other. If one point is not visible from the other then the slope is said to be *convex*.

FIG. 53.

Look at Fig. 53. First note the ring contours around the hill. We learn that the first portion of the upward slope from A to P is steep because the contour lines are close together. The second part of the slope is gradual, for the contour lines are farther apart. Thus the slope is convex. P is not visible from A.

Now examine the slope between P and N. Starting from P the

downward slope is steep. Towards *N* it becomes gradual. The slope is concave. *P* is visible from *N*.

It is, of course, easy to tell whether a slope is concave or convex by drawing a section (Fig. 54); but if we study contour maps we shall soon be able to dispense with this method.

FIG. 54. Method of Drawing a Section of a Contour Map.

Setting a Map. Maps are made for practical use. If we are going to use our ordnance maps out of doors we must learn how to set them. There are several ways of doing this.

(1) If we can see some object such as a church (*C*), and if we know the point on the map that represents our position (*P*) on the ground, we can arrange the map so that the line *PC* on the map corresponds to the line *PC* on the ground.

(2) If we are stationed on a piece of fairly straight road we can arrange our map so that the road as shown on the map corresponds in direction with the actual road on the ground. When we are at the junction of two or more roads, this method is an easy one.

(3) Setting a map with a compass. First set off from a point at the side of the map an angle representing the magnetic variation of the compass (see p. 13). The line so obtained will point to the magnetic north. Now place the compass on the map until the needle is at rest. Then lift the compass very carefully, and turn the map round

until the needle is parallel to the magnetic north line on the map. Replace the compass on the map. The arrow-head, indicating the Magnetic North, now points in the same direction as the magnetized end of the compass needle. The map will then be set.

Map Projections. As the earth is a sphere, its surface is curved and not flat. Thus this surface can only be correctly represented on a globe. It is impossible to show it with absolute accuracy on a plane, or flat surface, but it is possible to do so with relative accuracy.

When the curved lines of latitude and longitude on the globe are transferred to the flat surface of the map, such transference is called

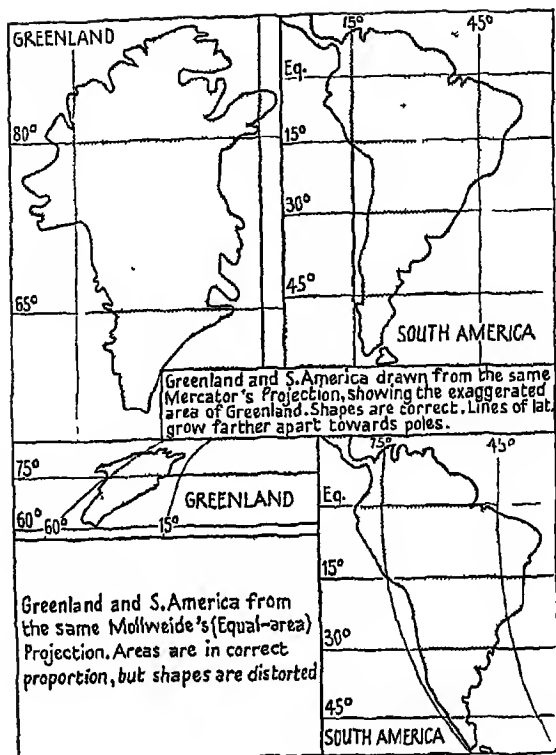

FIG. 57.

FIG. 58.

projection. There are various types of projections in which the lines of latitude and longitude are adjusted according to the type of map and the purpose for which it is required.

Some maps, like those drawn on Mercator's Projection, show *direction* correctly. This projection gives the correct shapes for only very small areas, and their comparative sizes are wrong. Such maps show great exaggeration towards the poles, the parallels of latitude growing farther and farther apart with increasing distance from the Equator. For example, Greenland, though only one-tenth the size, appears rather larger than South America on a Mercator map.

Other maps, known as *equal-area* maps, show the correct proportion of the different areas on the globe, but the shapes of such areas are incorrect, especially towards the margins of the map. In Fig. 57 compare the respective shapes and areas of Greenland and South America which are drawn on (i) Mercator's Projection, and (ii) Mollweide's (equal-area) Projection.

It is impossible to construct a map network, or *graticule*, so that both the directions and the areas are correct. It is, however, possible to draw maps on which the lines of latitude and longitude, forming the graticule, can be adjusted so as to lessen greatly the margin of error.

The construction of map projections involves advanced mathematical calculations, but the principles on which they are made are easily understood. They are perhaps best grasped by placing an electric bulb in the centre of a wire globe or one of glass on which have been drawn lines to represent the parallels of latitude and the meridians of longitude. These lines can then be projected on to a sheet of paper placed in various positions according to the type of projection which it is required to illustrate.

There are three main groups of map projections.

(1) **Projection on a plane tangent to, that is touching, the globe.** This type of projection is known as a *Zenithal Projection*. Imagine a light placed behind a wire or glass globe in various positions as indicated below. These positions will explain the principles of the three main types of Zenithal Projections, namely (a) *Gnomonic*, (b) *Stereographic*, and (c) *Orthographic*.

In Fig. 58 (a), (b), and (c) imagine a sheet of paper resting horizontally upon the globe so that it touches the North Pole, or in other words so that the plane of projection is tangent to the North Pole (N.P.).

In each of the three diagrams the radii from C (representing the earth's centre) are drawn at intervals of 15° . The points where they cut the respective circumferences represent the latitudes.

The projections are completed by drawing, as shown, (i) circles, with centres at the North Pole (N.P.), to represent the parallels of latitude; and (ii) straight lines, radiating from the North Pole, at intervals of 15° , to represent the meridians of longitude.

In Fig. 58 (a) the source of light (O) is at the centre (C). The radii are produced to meet the plane of projection XY . Compare the distance between the parallels of latitude 75° and 60° with that between 45° and 30° , and note that towards the Equator the exaggeration becomes steadily greater. On a Polar Gnomonic, such as that represented here, the Equator cannot be shown owing to this exaggeration.

In Fig. 58 (b), representing the stereographic projection, the source of light (O) is at the South Pole.

In Fig. 58 (c), representing the orthographic projection, the source of light (O) is supposed to be at infinity.

If the plane of the projection is tangent at the Equator, we obtain an *Equatorial Zenithal Projection*.

Zenithal Projections are frequently used to construct *equal-area maps*. Such maps are useful for showing the distribution of crops and the relative size of different countries, &c. In actual construction they are modified by adjusting the parallels according to the type of map. Among the best-known equal-area projections is *Lambert's Zenithal Equal-Area Projection*, frequently used in atlas maps.

Mollweide's Projection is a greatly modified projection in which the earth is represented as an ellipse. On such maps the major axis, representing the earth's equatorial circumference, is twice as long as the minor axis represented by a meridian of longitude drawn from pole to pole.

(2) **Conical Projections** are frequently used to represent relatively small areas, such as individual countries. The principles on which this projection is based are illustrated by Fig. 59 (a). A sheet of paper, folded to form a cone, rests on a glass globe, so that its apex is over the North Pole. The globe has a light in the centre, and on it are marked lines representing the parallels of latitude and the meridians of longitude. Shadows of these lines are projected on to the cone, upon which they are traced. The cone is then unfolded, as shown in Fig. 59 (b). It will be noticed that the meridians of

FIG. 59. Conical Projection.

FIG. 60. Cylindrical Projection.

longitude are straight lines diverging from a common centre, and that the parallels of latitude form arcs of concentric circles.

FIG. 61.

FIG. 62.

Figure 61 (a) represents a cone tangent to, or touching, a globe along latitude 30°, which is the *standard parallel*. The apex (X) of the cone is directly over the North Pole (N). At latitude 30°, and for some distance on either side, the map will be approximately

correct and will not differ greatly from the outline on the globe. Fig. 61 (b) shows the projection partly drawn. One of the best-known conical projections is *Bonne's Projection*.

A modified form of conical projection, with two standard parallels, instead of only one, is frequently used. The cone is supposed to *cut* the globe along two lines instead of merely touching its surface along one line. In Fig. 62 (a) the cone is shown cutting the surface along

Globular

FIG. 63.

Mercator

FIG. 64.

parallels 30° and 45° . The map will be correct along the standard parallels, but beyond them the latitude distance is exaggerated, while between them it diminishes somewhat.

(3) **Cylindrical Projections.** The principle on which these projections are based can be best understood by placing a cylinder over a glass globe with a light in the centre. Fig. 60 (a) shows the cylinder about to be placed over the globe. In Fig. 60 (b) we can see the lines projected on the cylinder which is now in position over the globe. It will be noticed that (a) the parallels of latitude near the light, in the centre of the globe, are relatively close together, but that they grow farther and farther apart towards the poles; (b) the meridians are parallel lines equidistant from each other, and consequently, as they do not meet at the poles, the Polar Region cannot be properly shown on maps drawn on a cylindrical projection; (c) the lines of latitude and longitude intersect at right angles.

One of the best-known cylindrical projections is *Mercator's Projection*, which is of especial use to mariners and navigators of aircraft because it shows the correct *direction*. Its disadvantage is the great exaggeration towards the Poles, which are not, as we have seen (Fig. 57), actually shown on the map. The exaggeration of scale towards the poles is well illustrated by Fig. 63, showing a monk's head drawn on a globe, and Fig. 64, the head as it would appear in Mercator's Projection.

Like most projections Mercator's Projection is modified. The principle of its construction is that the exaggeration from north to south is made equal to that from east to west. This means, for example, that latitude 60° , actually half the length of the equator, is doubled in length, and that distances north and south at this point are also doubled. On Mercator's Projection the only *great circles* (see p. 12) represented by straight lines are the equator and the meridians of longitude.

EXERCISES

1. What do you mean by the *scale* of a map? What are the chief scales used on British ordnance maps?
2. What is a *representative fraction*? Express as representative fractions the scales of maps on which (a) 1 mile is represented by $\frac{1}{4}$ inch, 1 inch, and 25 inches; and (b) 360 miles are represented by 1 inch. Which of the above maps is a small-scale map?
3. A valley running roughly north to south is 10 miles long. It is bordered by hills rising steeply on the west to 1,100 feet, and more gradually on the east to 800 feet. A stream flows through the valley. After flowing for about 5 miles it receives two tributaries which flow into it from the north-west and north-east respectively. The main stream leaves the valley at a height of 100 feet and then winds across a plain to the sea, which is 10 miles away to the south. The river forms a delta at its mouth. (a) Draw a contour map to represent the above piece of country. Represent 4 miles on the ground by $\frac{1}{4}$ inch on your map. Insert contours every 100 feet. (b) What is the vertical interval of your map? (c) Express the scale as a representative fraction. (d) Is the mouth of the river strongly tidal?
4. A ridge measures 6 miles from east to west and 4 miles from north to south. The top is a plateau, about 350 feet above sea-level, measuring 2 miles from east to west and $1\frac{1}{2}$ miles from north to south. The slope of the ridge is much steeper on the south than on the north. Draw a contour map to represent the ridge. Insert contour lines for every 50 feet. Horizontal scale $\frac{1}{2}$ inch to 1 mile.
5. Draw contour sketches to show a peak, a pass, an escarpment, a rift valley, a canyon, and a fiord.

6. The lower portion of a W.-E. dale opens out on the east into a large river plain, which is rather below the 100 foot contour line. The dale itself varies from a mile to 3 miles broad, and is, as the crow flies, 16 miles long. Hills rise on each side of the dale; the highest point on the north side is 1,000 ft., on the south 800 ft. The dale is traversed by a river which has only one important tributary stream, *A*, entering from the north, not quite half-way down. Two smaller streams, *B* and *C*, enter, *B* from the north and *C* from the south, almost opposite each other, half-way between the mouth of *A* and the mouth of the dale. There are two market towns, *D* at the lower end of the dale and *E* 12 miles farther up. A large reservoir, *F*, has been built on stream *A*, and another, *G*, on stream *C*. Both reservoirs are about 400 ft. above sea-level. Construct a contour map to show this dale.

7. What do you understand by the term *map projection*? On what principle is Mercator's Projection constructed? What are (a) the advantages, and (b) the disadvantages of this projection?

8. Name a suitable projection on which to draw a map (a) to represent a relatively small area, such as England; and (b) to show the world distribution of wheat. In both cases give reasons for your answer.

PART II

EUROPE

CHAPTER X

GENERAL SURVEY OF EUROPE

WITH the exception of Australia, Europe is the smallest of the continents. It has an area of $3\frac{1}{2}$ million square miles—little more than one-fifth that of Asia, of which it forms a western peninsula. The Urals form no real physical boundary, and so closely are Europe and Asia united that when considered as a whole the term *Eurasia* is applied to them. On the north, the Arctic Ocean washes the shores of both continents, but while Europe looks towards the Atlantic and the Mediterranean, Asia faces the Pacific and Indian Oceans. Despite their marked physical resemblances, the differences in their development, civilizations, and peoples are so striking that this great land mass is rightly considered as two separate continents.

Europe has a more extensive coast-line, in proportion to its size, than any other continent. Few places are more than 400 miles from the sea, and even the heart of European Russia is only 700 miles distant from the ocean.

Fig. 65 shows that from the south-east of the Bay of Biscay shallow seas spread west of the British Isles and south-west of Norway. These seas cover the *Continental Shelf*, which is the name given to the *submerged margins of continents covered with relatively shallow water to a depth not exceeding 600 feet*. In geologically recent times this now submerged area formed part of an ancient land mass, and if the ocean bed were raised 600 feet, a portion of its former outline would be restored, and the British Isles would once more form part of the mainland. So shallow, indeed, are the North Sea and the Straits of Dover, that if St. Paul's Cathedral were sunk in the deepest part of the latter channel its dome would rise above the surface of the water.

The sinking of the continent, by allowing the ocean to extend through the North Sea into the Baltic, has opened up the heart of North-West Europe. Another result is that the lower courses of

many rivers have been converted into estuaries, at the head of which now stand some of the world's greatest ports. In the south, the Mediterranean and Black Seas provide a sea-way extending more than 2,000 miles from the Atlantic, while the Adriatic arm of the Mediterranean provides an outlet for the southern part of Central Europe.

The Mediterranean is divided into an *Eastern* and a *Western*

FIG. 65.

Basin, separated by a submerged ridge running from Tunis to Sicily. This ridge, together with a similar one across the Straits of Gibraltar, once formed a 'land-bridge' connecting Europe and Africa. The Mediterranean may, indeed, be regarded as a link rather than a barrier, and the lands around its shores—though forming parts of three separate continents—are unified by their climate, vegetation, and communications.

Relief. Europe falls into four main physical divisions.

(1) **The North-West Highlands** consist of the Highlands of Scotland and Scandinavia, both of which are disconnected fragments

of the ancient continent. They are composed of old, hard, crystalline rocks which, owing to long-continued denudation, have been so worn down that they now form irregular plateaus of the type known as dissected plateaus. Each of these regions is bordered by a steep fiorded coast on the west, and a plain on the east.

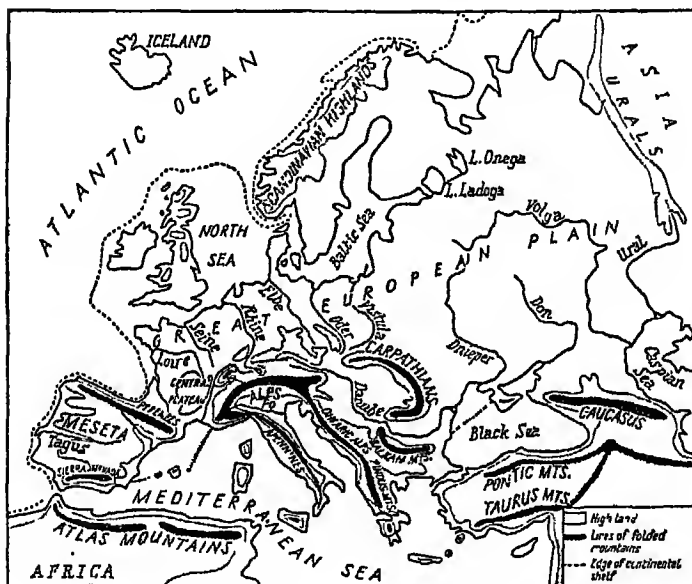

FIG. 66. Europe : Relief.

(2) To the south of these dissected plateaus lies the **Great European Plain** extending from the shores of the Bay of Biscay through Northern France, Belgium, Holland, Northern Germany, and Poland, into Russia, whence it merges into the plains of Asia.

(3) **The Central Uplands of Europe** stretch across the centre of the continent. Once they formed a continuous chain, but now only detached and much-denuded fragments remain. Considerable faulting, or fracturing, has taken place. Some areas have been up-lifted to form crust-blocks : others have subsided. Among the chief of these elevated blocks are the Meseta of the Iberian Peninsula,

the Central Plateau of France, the Highlands of Brittany, and those of Cornwall and South-West Ireland; the Ardennes, the Rhine Highlands, the Vosges, and Black Forest Ranges flanking the Rift Valley of the Rhine; the Bohemian Uplands, and the Rhodope Highlands. The islands of Corsica and Sardinia, margining the Tyrrhenian Sea, are isolated crust-blocks.

(4) **The South European Fold Mountains**, geologically much younger than the Central Uplands, form part of a great system of

FIG. 67. Note (a) the sea routes leading to the Mediterranean; (b) the routes leading (through the passage between Sicily and Africa) from the Western to the Eastern Basin; (c) the land routes leading to the Mediterranean Sea.

fold mountains extending from the Cantabrians, across Europe and Asia to the Himalayas. The chief European mountains in this system are the Cantabrians, Pyrenees, Alps, Carpathians, Transylvanian Alps, Balkan Heights, and the Caucasus. From the Alps two other lines of fold mountains trend southward. (i) The Apennines, which form the backbone of Italy, are continued through Sicily, whence the folds form the Atlas Mountains of Northern Africa. They then curve sharply and may be traced through the Sierra Nevada Mountains of Southern Spain, reappearing in the Balearic Islands. (ii) The folds forming the Dinaric Alps, and their continuation the Pinus Mountains, are continued through Crete to the Taurus Mountains in the south of Asia Minor.

These fold mountains enclose the Plain of Lombardy, the Plain of Hungary, and the Western Basin of the Mediterranean.

Broad 'gates' in the Central Uplands and the European Fold

Mountains form important channels of communication. Among the chief are: the Gate of Carcassonne between the Pyrenees and the Central Plateau of France; the Rhone-Saône valley between the Central Plateau and the Alps; the Burgundian Gate between the Jura and the Vosges; and the Moravian Gate between the Bohemian Plateau and the Carpathians. The most important Alpine passes are the Mont Cenis, the Simplon, the St. Gotthard, and the Brenner.

Among the leading 'sea-gates' are the Straits of Dover leading from the English Channel to the North Sea, and the Skagerrak, Kattegat, and the Great Belt linking the North Sea with the Baltic. In the Mediterranean, the Straits of Gibraltar lead from the Atlantic to the Western Basin of that Sea, while the Sicilo-Tunisian Gate gives access to the Eastern Basin, which is linked with the Black Sea by the Dardanelles, the Sea of Marmara and the Bosphorus.

Rivers. Though the rivers of Europe cannot compare in length or volume with those of Asia, the Americas, or Africa, they are among the most important in the world. Many of them are navigable, and at the heads of their estuaries and along their banks stand some of the world's chief cities.

The Rhine (760 miles), the Rhone (490 miles), and the Po (415 miles) all rise in the Alps; and though the source of the Danube (1,700 miles) is in the Black Forest Range, some of its chief tributaries rise in the Alps. But though the headwaters of these four rivers are comparatively near one another, they all flow in different directions, and during part of their courses their valleys form routes leading from Central Europe to the sea. The Rhine flows into the North Sea, the Rhone into the Mediterranean, the Po into the Adriatic, and the Danube into the Black Sea.

The Vistula (630 miles), Oder (580 miles), and Elbe (690 miles) rise in the Central Uplands and flow across the European Plain, the two former rivers entering the Baltic, the latter the North Sea.

In France the Seine (480 miles) pours its waters into the English Channel, and the Loire (570 miles) and the Garonne (350 miles) into the Bay of Biscay. In the Iberian Peninsula the Douro (460 miles), the Tagus (510 miles), and the Guadalquivir flow into the Atlantic, and the Ebro (420 miles) into the Mediterranean.

The Dniester (700 miles), the Dnieper (1,200 miles) and the Don (1,200 miles) all fall into the Black Sea. The Volga (2,200

miles), Europe's longest river, winds south across the Russian Plain and runs into the land-locked Caspian, the centre of a large inland drainage area. The Pechora and the Dvina flow into the Arctic.

The Great Ice Sheets. Northern Europe was once covered by a great Ice Sheet, so thick indeed that only the highest peaks remained above its surface. At times during the Ice Age there were periods when the climate was warmer and the ice receded. Such periods are called Interglacial Periods.

During its greatest advance the Ice Sheet spread slowly southward until Ireland, Scotland, and England as far south as the Thames were buried beneath it. To the east, this sheet advanced from Scandinavia across the Great European Plain, stretching from the present mouth of the Rhine, eastward beyond the Vistula.

At the same time great glaciers descended from the Alps and travelled northward across the plain. But the Ice Sheet coming from the north and these glaciers advancing from the south did not meet, and between them remained a fertile strip of varying width not covered by ice. This belt spreads from Picardy, in France, across the south of the German Plain, and thence through Poland into Russia. Like the plains of Northern China, it is covered with a light sandy soil called *loess*, in all probability wind-borne, which forms a rich agricultural soil. When the Ice Sheet finally retreated it left behind clays, sands, and gravels, as well as rocks and boulders which had been carried by glaciers. Many of the latter, called erratics, or 'wanderers', are found in such regions as the British Isles north of the Thames, and the North German Plain.

Climate. Europe extends from latitude 70° N. to 35° N., and thus nearly the whole continent lies in the temperate zone, and in the *westerly variable wind belt*. Owing to (a) the many inlets and seas opening from the west, and (b) the absence of a north-south mountain barrier, the westerly winds carry the influence of the Atlantic a considerable distance inland, though this influence steadily diminishes towards the east, with increasing distance from the ocean.

The Mediterranean Lands, lying in lower and warmer latitudes, are isolated from the rest of Europe by mountains whose general direction is from west to east. These mountains shelter the greater part of the Mediterranean region from cold influences from the

north, but they do not prevent moderating oceanic influences reaching it from the south-west. In winter, however, cold north winds from Russia sometimes blow over the Aegean and Greece.

Temperature. In *winter* the waters of the Atlantic are comparatively warm, for they retain for a time the heat they have been

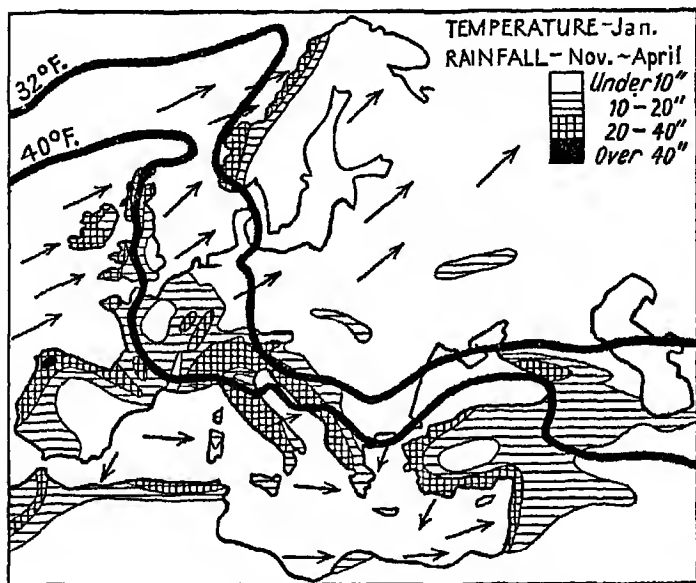

FIG. 68. Europe: Winter Temperature and Rainfall.

steadily absorbing during the summer. In the northern winter, when the sun is overhead between the equator and the Tropic of Capricorn, the heat, wind, and rainfall belts shift south. At this season all Europe lies in the westerly variable wind belt. These winds waft the warm waters of the *North Atlantic Drift* across the northern part of that ocean, and the waters, by warming the winds blowing over them, raise the temperature of Western Europe, causing a mild winter climate (Fig. 68). In winter, temperatures decrease from west to east.

In *summer* the sun is overhead in the Northern Hemisphere. Its rays now shine down more directly in the south than in the north,

and their power is therefore much greater in the former region. The ocean has not yet attained its maximum heat and is comparatively cool, and thus regions near the coast are cooler than those in the interior, where the oceanic influence is but little felt. *In summer,*

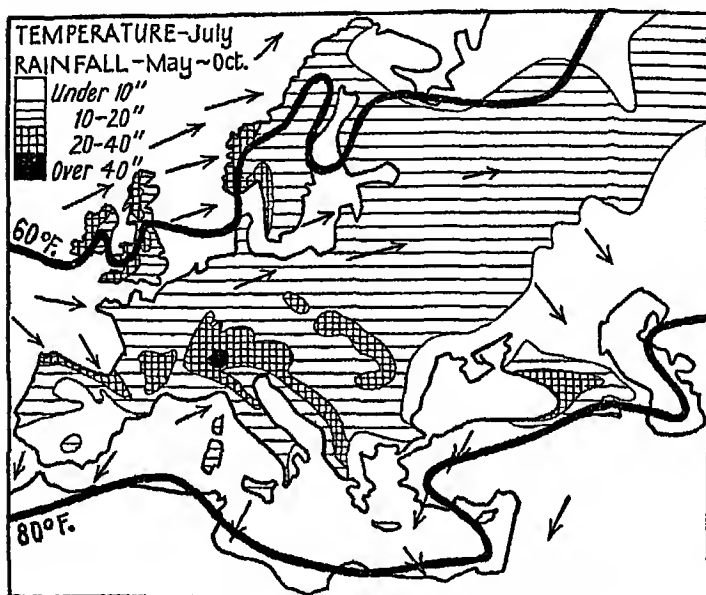

FIG. 69. Europe: Summer Temperatures and Rainfall.

temperatures decrease from south to north, and the isotherms run from south-west to north-east (Fig. 69).

Rainfall. In *winter*, as we have already seen, Europe lies in the westerly variables wind belt. The mountainous regions of the North-West are the wettest: South West-Norway, the west of Scotland, the English Lake District, the Welsh Uplands, and North-West Spain receive the heaviest rain. Central and Eastern Europe are comparatively dry.

In *summer* the prevailing winds in Western Europe still blow from the west, bringing rain to the north-western part of the continent. As Central and Eastern Europe are regions of considerable heat and low pressure, the influence of the winds extends farther inland in

summer than in winter (when high-pressure conditions prevail). Thus most of the rain in Central and Eastern Europe falls in summer, when rainy periods alternate with hot dry spells.

FIG. 70. Europe: Climatic Belts (after Kendrew).

But as the wind belts have moved north, with the apparent movements of the sun, the Mediterranean Lands now lie on the edge of the North-East Trade Wind area. They are in the Dry Belt and receive little rain, though sometimes thunder-storms with heavy downpours occur.

It is important to note that *a considerable amount of the rainfall, especially in Western Europe, is brought by cyclones (depressions), which usually move from west to east across the continent. They are more frequent in winter than summer.*

Four climatic belts may be distinguished (Fig. 70).

(1) *North-Western Europe* (including the British Isles), which has cool summers, mild winters, and rain at all seasons, with an autumn maximum.

(2) *Central Europe*, which has warm summers, cold winters, and rain at all seasons, but most in summer.

(3) *Eastern Europe*, whose climate is somewhat similar, but more extreme than that of Central Europe: temperatures are higher in summer, lower in winter and nearly all the rain falls in summer.

(4) *The Mediterranean Lands*, where the summers are warm, dry, and brilliantly sunny, and the winters mild and showery.

Natural Vegetation and Crops. The kind of vegetation depends on the relief, soil, and climate; and of the climatic factors temperature and rainfall are the chief. Moreover, the sufficiency of rain in any region depends mainly on evaporation, though given favourable circumstances deficient rainfall can be remedied by irrigation.

With the exception of the Tundra, the natural vegetation zones of Europe have been greatly modified by Man (Fig. 71).

(1) The *Tundra* stretch from the higher parts of Scandinavia along the Arctic coast-lands of Russia.

(2) The *Cool Forests*, south of the Tundra, contain birch and coniferous trees like pine, larch, and spruce, which are adapted to withstand the low rainfall and long severe winters. In the cleared areas, rye, oats, barley, and roots are grown.

(3) The *Deciduous Forests* (with conifers at higher elevations) lie south of the Cool Forests. Beeches, oaks, and other broad-leaved trees found in these forests require rain at all seasons, and it is interesting to note that for this reason they are not found in the Mediterranean Lands owing to the summer droughts. The deciduous woodlands, which once covered the greater part of Western and Central Europe, have now been extensively cleared for cultivation. Cereals include wheat and barley: among the chief roots are potatoes and sugar beet.

(4) The *Steppes* have hot summers, cold winters, and sufficient rainfall for grass (and cereals), but not for trees. The chief steppe areas, which are the leading wheat- and maize-growing districts in Europe, are in Southern Russia and the Hungarian Plain.

(5) In the *Evergreen Forests* of the Mediterranean Lands, trees and shrubs are adapted to withstand the dry summers. Characteristic

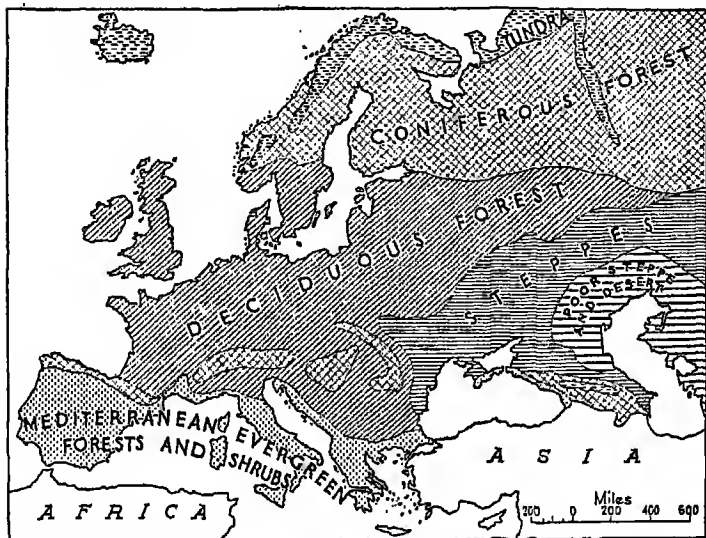

FIG. 71 Europe: Natural Vegetation.

products are the holm and cork oak, the olive, vine, orange, and lemon. Maize and wheat are the main cereals, while rice is grown in hot districts, on irrigated lands.

Distribution of Minerals. Europe has ample supplies of coal and iron. Outside Britain, the main *coal-fields* are the Ruhr, the Franco-Belgian, the Silesian, and the Donetz Basin (U.S.S.R.). *Iron-ore* is obtained chiefly from France and Luxembourg, Sweden, the U.S.S.R., Germany and Spain. About 10 per cent. of the world's *petroleum* comes from the U.S.S.R. Some is obtained from Rumania and Austria.

FIG. 72. Europe Population

Hydro-Electric Power. The chief European countries using this form of energy are Italy, France, Sweden, Norway, Switzerland, the U.S.S.R., Germany, and Spain.

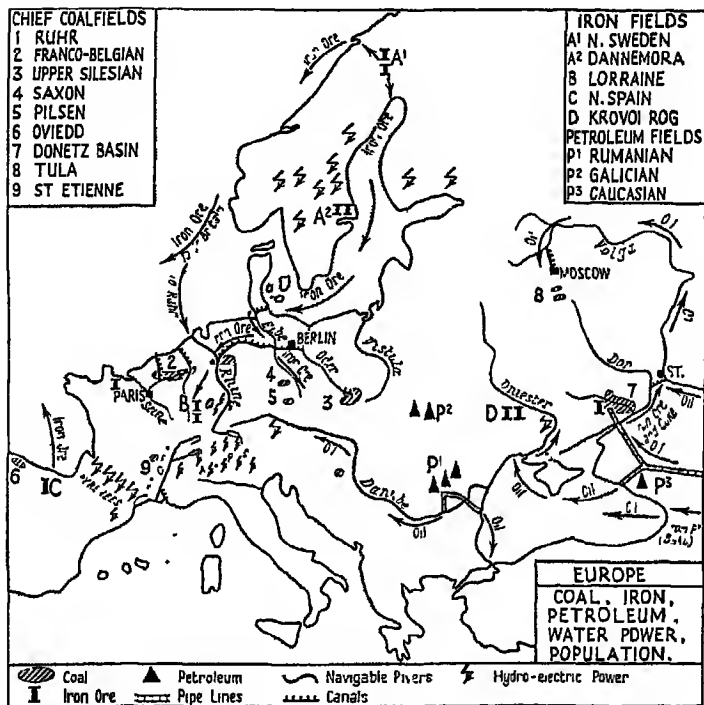

FIG. 73. Europe: Distribution of Minerals.

Distribution of Population. As will be seen from Fig. 72, the most densely peopled areas in Europe (excluding Great Britain) are (i) the industrial areas, centred on the Franco-Belgian and German coal-fields; (ii) the coast-lands of Belgium and Holland; (iii) the Rhine Valley; (iv) the North Italian Plain; and (v) most of the Mediterranean coast-lands of Spain, and those of Italy, including Sicily.

In addition to the mountain areas, sparsely peopled regions are (i) the Meseta; (ii) Central France; (iii) much of the Balkan

Peninsula; and (iv) the Pripet Marshes, the south-east, and the north of European Russia.

Communications. Europe, with her indented coast-line, is well placed for ocean trade. On the west she faces the Atlantic, the world's busiest ocean; on the south the Mediterranean, through which goes the seaway, via the Suez Canal, to India, the Far East, and Australia. Moreover Europe has a finer internal transport system than any other continent, facilities being best in the west but declining towards the east. From Paris important railways run (a) east via Prague to Warsaw; (b) by Trieste and Belgrade to Istanbul; (c) by Alpine routes to Milan and Rome; (d) via Basle to Vienna; and (e) south-west to Madrid. The Rhine is the chief inland waterway, but much trade is carried on along the Danube, and by canals in France, Belgium, Holland, and Germany. Europe is linked by air with all parts of the world. Paris, Brussels, Amsterdam, and Rome are great air junctions.

Political Divisions. The countries of Europe fall into five main divisions, based chiefly on climatic characteristics.

(1) Countries of Western Europe—the British Isles, France, Belgium, Holland, and Switzerland.

(2) The Baltic Lands and their Margins—Denmark, Norway and Sweden; Finland; Russia; and Germany and Poland.

(3) The Danube Lands—Czechoslovakia, Austria, Hungary, Yugoslavia, Bulgaria, and Rumania.

(4) Mediterranean Europe—the Iberian Peninsula (Spain and Portugal), Italy, Albania, Greece, and Turkey in Europe.

EXERCISES

1. Europe may be divided into four major physical divisions. (a) Name these divisions. (b) Describe the physical relief of *one* of them, illustrating your answer by a sketch-map.

2. Draw a map of the Mediterranean Sea. Shade the high land surrounding this sea. Show by arrows, and name (i) three land- and two water-routes leading to the Western Basin, and (ii) three land-routes and one water-route leading to the Eastern Basin.

3. What part of Europe, excluding the British Isles, was once covered by the Ice Sheet? What effect did the Ice Sheet have on the topography of the land and on the soils of the area it covered?

4. What do you mean by the term *continental shelf*? Off what part of Europe is the continental shelf broadest? What advantages has this given to this area?

5. On an outline map of Europe (a) insert the July isotherm 70°F. , and the January isotherm 32°F. (b) Selecting appropriate phrases from the following, summarize on your map the summer and winter temperatures of the four temperature divisions into which the isotherms you have drawn divide Europe:

- (i) *Cool Summers : Mild Winters ;*
- (ii) *Cool Summers : Cold Winters ;*
- (iii) *Warm Summers : Cold Winters ;*
- (iv) *Hot Summers : Mild Winters.*

6. (a) On a sketch-map mark and name the chief vegetation zones into which Europe may be divided. (b) Give a short account of the natural vegetation and crops in any *two* of them.

7. How do you account for the following facts: (a) Palm trees grow out-of-doors in the Isle of Man, but they are not found in similar latitudes in Eastern England; (b) Rice can be grown in the Plain of Lombardy, but olives cannot be cultivated there; (d) in France the vine is not grown for wine-making north of the Loire Valley?

8. Europe may be divided into four major climatic divisions. (a) Name these divisions. (b) Each of the towns, for which climatic data are given below, is situated in one of the major divisions. State, giving your reasons, in which division you think each town lies.

		J.	F.	M.	A.	M.	J.	J.	A.	S.	O.	N.	D.
A	Temp. ° F.	15	17	24	36	48	59	64	61	51	40	29	20
	Rain, inches	0.9	0.8	0.9	0.9	1.7	1.8	2.7	2.7	2.0	1.7	1.4	1.2
B	Temp. ° F.	52	56	60	64	70	78	85	85	78	68	60	53
	Rain, inches	2.6	2.0	2.6	1.8	1.7	0.6	0.0	0.1	0.8	2.1	3.1	2.5
C	Temp. ° F.	41	43	47	53	58	64	68	68	64	55	47	41
	Rain, inches	2.5	2.0	2.3	2.5	2.8	2.8	1.9	2.0	2.6	3.6	3.1	2.7
D	Temp. ° F.	31	33	37	46	55	62	65	63	57	48	38	33
	Rain, inches	1.5	1.3	1.7	1.4	2.0	2.0	3.1	2.2	1.8	1.8	1.6	1.7

9. Select *one* of the above towns in question 8 and represent the temperature and rainfall by means of a diagram.

CHAPTER XI

GENERAL SURVEY OF THE BRITISH ISLES

THE British Isles cover approximately 121,000 square miles. Politically they consist of the United Kingdom of Great Britain and Northern Ireland, and the Irish Republic.

Before the great discoveries of the sixteenth and seventeenth centuries the British Isles lay on the edge of the known world. They were an outpost of Europe, islands of no great importance, looking towards that continent from whence had come most of their peoples, their language, law, and religion. But after the discovery of America, Britain was no longer situated on the outskirts of the world, but at its centre, for now she lay athwart the ocean highway leading from the Old World to the New. Her favourable location facilitated the growth of her shipping and ocean commerce, the expansion of her overseas territories, and the spread of the English language throughout the globe.

Britain owes much to her insular position. To it is due that temperate climate which accounts in large measure for the activity of her people; that security which until the development of aircraft enabled the British for nearly 900 years to carry on their occupations in their island-home with but little interference from the outside world; and that love of the sea which has encouraged a maritime rather than a continental outlook towards world affairs.

The situation of the British Isles on the continental shelf is a distinct advantage. The subsidence which caused the formation of the shelf allowed the sea to penetrate deeply into the British Isles, and to convert the lower courses of many rivers into estuaries up which at each high tide ocean-going vessels can travel to great ports, such as London, Liverpool, and Glasgow.

But despite the growth of her sea-trade, Britain remained until the eighteenth century primarily an agricultural and stock-rearing country. Then, towards the middle of that century, the invention of the steam engine and of power-driven machinery, gave Britain the lead in the Industrial Revolution—a lead which, in spite of foreign competition, she has never wholly lost. One thing alone enabled her to take full advantage of the mechanical inventions of her people,

and that was the presence of abundant supplies of *coal*, and it is to coal more than to any other geographical factor that Britain owes her economic development.

Relief. The surface of the British Isles has been greatly worn away by denudation. At the present time running water is the principal agent of erosion, but in past ages the Ice Sheet, which covered the region north of the Thames, did much to mould the surface of the land. The glaciers of the Ice Age played a great part in fashioning the U-shaped valleys now to be seen in parts of the Scottish Highlands, the Lake District, and the Welsh Uplands; while the narrow mountain lakes and sea-lochs which indent the north-west coast of Scotland were formed, in part at least, by glacial action. The Ice Sheet also left behind masses of waste material, such as the boulder clay, sands and gravels.

In the British Isles there is little land over 3,000 feet. The north and west are chiefly uplands whose old, hard rocks form thin, infertile soils. The east and south are mainly lowlands, whose younger rocks have weathered to form fertile soils.

In Great Britain there are a number of well-marked physical divisions (Fig. 74). The *Scottish Highlands*, in the north, are the most extensive upland area in the British Isles. They form a dissected plateau, deeply trenched by valleys whose south-west to north-east direction is well seen in Glenmore, the narrow rift separating the North-West Highlands from the Grampians. The *Midland Valley of Scotland* is a broad rift valley lying between the Grampians and the *Southern Uplands*. In the south-east the latter merge into the Cheviots, beyond which high land continues to the Tyne Gap.

The *Pennines*, which project southward into England, may be divided into the Northern Pennines, extending from the Tyne to the Aire Gap, and the Southern Pennines, which stretch from the Aire Gap to the Peak District of Derbyshire. On the west, the Pennines are linked by Shap Fell with the dome-like *Cumbrian Mountains* of the Lake District.

The *Welsh Uplands*, a much denuded highland area, extend from the narrow coastal plain of North Wales to the broader lowlands of Glamorgan. The *South-West Uplands of Devon and Cornwall* consist of Exmoor and the granite masses of Dartmoor and Bodmin Moor, separated by the valley of the Tamar.

The *English Plain*, the most extensive lowland area in Great Britain, may be divided into a number of regions.

(a) The *Midland Plain* of New Red Sandstone extends through the Midland Gate into Cheshire and Lancashire, and east of the Pennines into Yorkshire.

(b) The *Scarplands* stretch from Dorset to Yorkshire. They consist of roughly parallel oolitic limestone and chalk hills, between which lie clay vales. On the north-west the ridges fall by steep escarpments, but on the south-east they descend to the vales by long gentle dip-slopes. Follow the ridges on a map. The chief limestone ones are the Cotswolds, Northampton Heights, Lincoln Edge, and the North York Moors. The principal chalk ridges are the Western Downs, the White Horse Hills, the Chilterns, the East Anglian Heights, the Lincolnshire Wolds, and the Yorkshire Wolds. From the Western Downs, the North and South Downs run eastward.

(c) The *Fens* and *East Anglia*.

The downfolds forming (d) the *London Basin*, and (e) the *Hampshire Basin*.

(f) The *Weald* was formed by the erosion of a dome of chalk between the North and South Downs, which are now the only remaining portions of this former upfold.

Ireland consists of a Central Plain, floored with limestone, surrounded by detached uplands between which the lowlands reach the sea.

Rivers. Apart from the estuaries, whose importance can scarcely be overestimated, the rivers of Britain are of little use for navigation, and except for the Shannon and some Scottish and Welsh (in Snowdonia) streams few have been harnessed for hydro-electric power.

As most of the mountainous areas in Great Britain lie closer to the west coast than the east, the rivers flowing into the Atlantic and the Irish Sea are (except for the Severn) shorter than those running into the North Sea. Trace on a map the main watershed running from the north-west of Scotland to the centre of the Southern Uplands, and thence along the west side of the Pennines.

The Scottish Rivers. The Clyde (106 miles) is the only important river flowing westward to the sea. On the east the chief streams entering the North Sea are the Spey (96 miles), Dee (87 miles), Tay (100 miles), Forth (60 miles), and Tweed (96 miles).

The Pennine Divide. From the Northern Pennines, the Eden

(draining Lakes Haweswater and Ullswater), Lune, Ribble, and Mersey flow into the Irish Sea. The Trent (150 miles) also rises on the west side of the Pennines, but curves round their southern end,

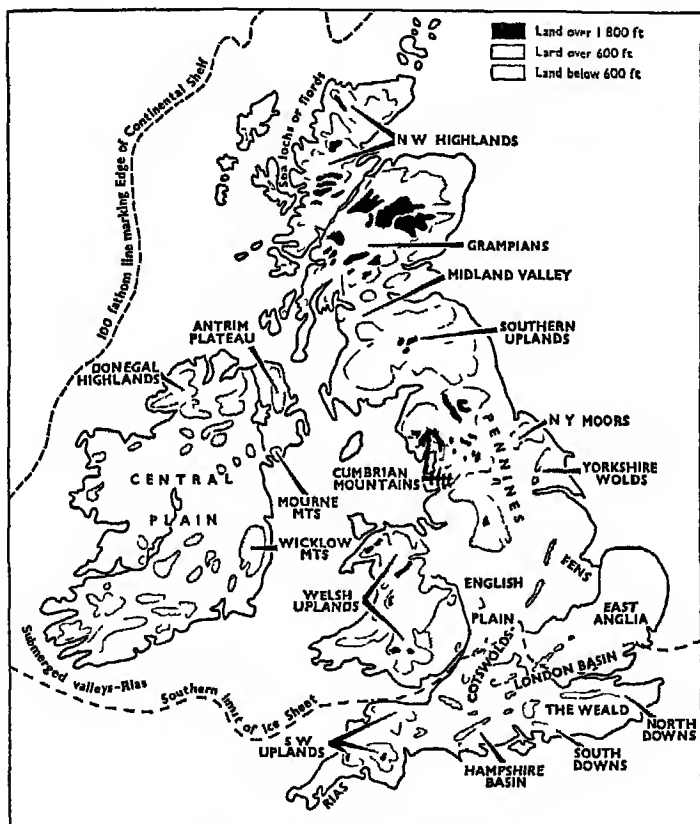

FIG. 74. British Isles: Physical Features.

turns north, and enters the Humber. The Yorkshire Ouse (120 miles), which also enters the Humber estuary, gathers tributaries from the eastern slopes of the Pennines. Of these the Aire has eaten back its way through the Uplands to form the *Aire Gap*, which, like the *Tyne Gap* to the north, is an important channel of communication.

The Tyne, Wear, and Tees flow in an easterly direction from the Pennines to the North Sea.

The *Rivers of the Scarplands* include the Great Ouse (145 miles), Nen, Welland, and Witham. After leaving the Scarplands, the Thames (215 miles) traverses the London Basin, flowing into the North Sea through a wide estuary.

The *Rivers of the South-West* include the Parret, Exe, and Tamar whose 'drowned' valley (a ria) forms Plymouth Sound.

Rivers of the South-East. On your map, follow the watershed of South-East England through the White Horse and Hampshire Downs, and thence through the Forest Ridge of the Weald. Among the streams flowing into the English Channel are the Salisbury Avon; the Test and the Itchen both entering Southampton Water; and the Arun and Sussex Ouse, flowing through gaps in the South Downs. Through similar gaps in the North Downs the Stour flows into the North Sea, the Medway into the Thames estuary, and the Wey to the Thames.

The Welsh Watershed. From the Welsh Uplands the Dee flows into the Irish Sea, the Severn (220 miles) and the Wye into the Bristol Channel. To the west of the lower Wye other streams—the Usk, Taff, and Tawe—flow into the Bristol Channel. They are mainly important because (i) Newport, Cardiff, and Swansea stand at their respective mouths, and (ii) their valleys form routes leading to the South Wales coal-field.

Irish Rivers. The Shannon (250 miles), the longest river in the British Isles, flows sluggishly across the Plain, but after leaving Lough Derg descends so rapidly to the sea that its waters are used for hydro-electric power.

Climate. On the west the British Isles face the Atlantic; on the east they front the North Sea. The prevailing *south-west winds* cause a surface drift of warm water to flow across the North Atlantic towards the British Isles. This water increases the temperature of the winds blowing over it, and thus allows them to absorb more moisture than would otherwise be the case. To these warm, moisture-laden south-west winds is due, in large measure, the equable climate of the British Isles.

Temperature. *In summer the main factor affecting the temperature of the British Isles is the greater directness of the sun's rays in the south*

compared with the north. The secondary factor is the influence of the ocean. In July, as the Atlantic is comparatively cool, the south-west winds, which are cool too, decrease the temperature of the coastal regions. On the other hand, the shallow North Sea is warmed more quickly than the deep Atlantic, and though it has a slight cooling effect on the land, this effect is not so great as that of the ocean on the west. *In summer, temperatures decrease from south to north, but the regions near the coast are cooler than those inland.*

FIG. 75. British Isles: Temperature.

In winter the sun is still higher in the sky in the south than in the north, but as it is overhead in the Southern Hemisphere its rays have little warming effect on the British Isles. The *primary factor affecting the winter temperature of the British Isles is the influence of the ocean.* In January the land has lost its summer warmth, but the ocean still retains some of its heat. At this season the warmer regions are those facing the Atlantic. This ocean is warmer than the North Sea, which, owing to its relative smallness and shallowness, loses its heat comparatively quickly. In winter the interior of Europe is very cold, and a region of high pressure. Easterly winds blowing from this high pressure system have a distinct cooling effect on the east of the British Isles. In January South-East England, the nearest point of which is only 20 miles from the Continent, is cooler than North-West Scotland, where the warming influence of the Atlantic prevails. *In winter the west of the British Isles is warm, the east is cold.*

Temperatures decrease from west to east, and therefore the isotherms run from north to south.

FIG. 76. British Isles: Mean Annual Rainfall.

Rainfall. (Fig. 76.) The prevailing south-westerly winds cause heavy rain in the mountainous west of the British Isles. When these winds descend on the leeward side of the uplands they have already lost much of their moisture and are comparatively dry winds. In their descent they are also warmed somewhat, with the result that they are (i) mild winds, and (ii) being warm retain more moisture

than cool winds. Thus on the leeward side of the mountains there is usually a pronounced *Rain Shadow*.

The highest parts of the British Isles are the wettest parts: North-West Scotland, the Lake District, the Welsh Mountains, the uplands

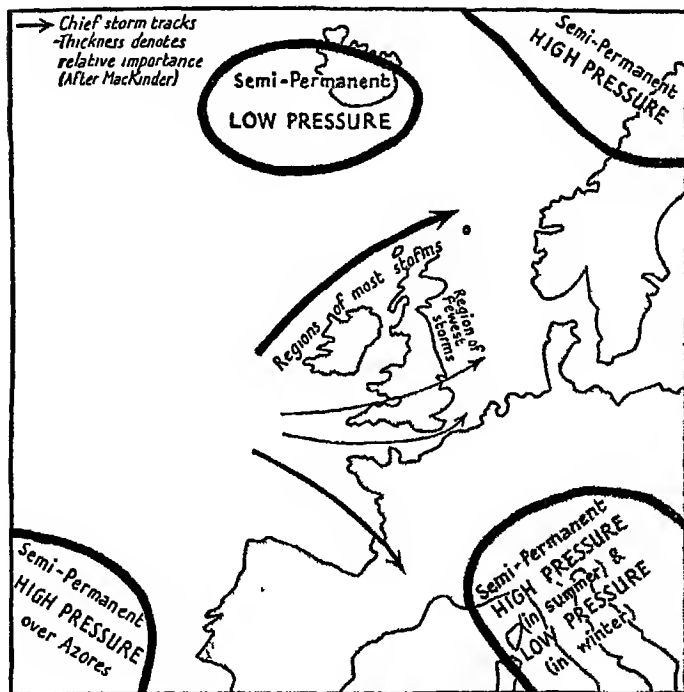

FIG. 77. British Isles: Weather.

of South-West England, and South-West Ireland have most rainfall. Ben Nevis has a mean annual rainfall of 171 inches; and Snowdonia, with 200 inches, is one of the wettest areas in Europe.

The east winds, blowing over the narrow North Sea, gather less moisture than the westerlies. Eastern England is flat, but even low hills receive greater rainfall than the valleys. The mean annual rainfall at both Nottingham and Cambridge is only 22 inches.

Weather. *Climate is average weather.* The weather in the British Isles is affected mainly by *cyclones* which usually approach from the North Atlantic. To a lesser degree British weather is influenced by *anticyclones*. Both are represented on maps by *isobars*. Favourite tracks of cyclones are (i) along the north-west of our islands; (ii) up the English Channel; and (iii) across the south of England (Fig. 77). Cyclones usually come in series, being most intense and frequent

FIG. 78. A Typical Cyclone Over the British Isles.

in autumn and winter. Rain, falling mainly in the central region, is continuous on the *warm front* with southerly winds, and squally on the *cold front* where there are northerly winds (see p. 60). In cyclonic periods the general weather conditions are unsettled and winds are variable (Fig. 78).

It is only in *anticyclonic periods* that the weather is really settled. As can be seen from Fig. 79, the air flows outwards from the high-pressure area in the centre: as it is compressed and warmed in descending it is relatively dry, and the weather is fine. In summer the days are sunny, there is an absence of cloud, and temperatures are high. In winter the days are cold and bright, the nights clear, frosty, and starlit. In winter, cold heavy air tends to collect in the

valleys, where it is scarcely stirred by the light anticyclonic winds. Thus in such lowland regions the moisture from the damp ground is often precipitated as fog, and it is no uncommon thing to find brilliant sunshine on the hills while the valleys are fog-bound.

Climatic Zones.¹ The July isotherm 60° F. and the January isotherm 40° F. divide the British Isles into four climatic zones (Fig. 80).

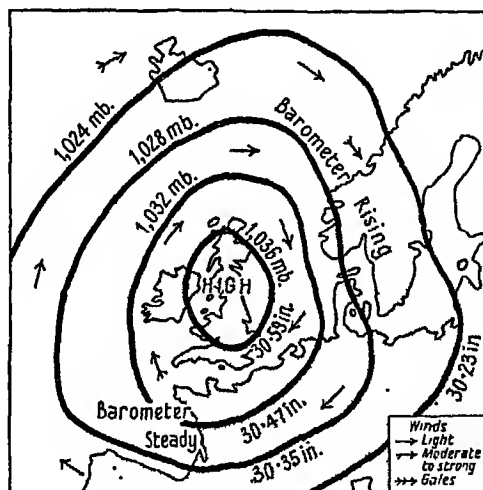

FIG. 79. A Typical Anticyclone.

(1) *The North-West*, where oceanic influences are greatest, has cool summers, mild winters, and heavy rain.

(2) *In the South-West* the summers are warm, the winters mild, and the rainfall moderate. This region has the most equable climate in the British Isles.

(3) *The South-East* has warm summers, cold winters, a low rainfall, and the general climatic conditions are relatively extreme.

(4) *In the North-East* the summers are cool, the winters cold, but the rainfall is slightly more and the climate is somewhat less extreme than in the south-east.

¹ After Mackinder.

Natural Vegetation. At one time the greater part of the British Isles was covered with deciduous forests and only the higher and more exposed parts were devoid of trees. To-day, however, only about 5 per cent. of Great Britain and less than 2 per cent. of

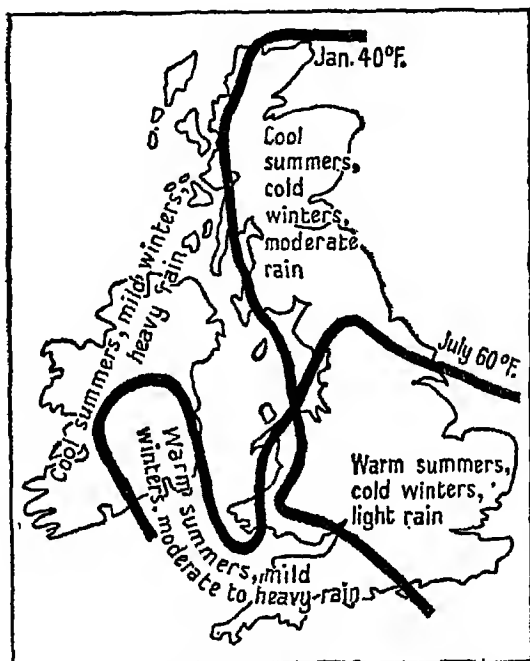

FIG. 80. British Isles: Climatic Zones.

Ireland is clad with trees. Most of our former forests were cleared for pasture, arable land, and settlement, and especially for timber and fuel, mainly to provide charcoal for smelting iron ore. Our existing forests are largely the result of planting, such as that which took place in England in the eighteenth century, when, owing to the scarcity of timber due to the depredations of the iron industry, many private estates and Crown Lands were afforested. Much timber was felled during the First and Second World Wars, but the Forestry Commission has taken over more than 1½ million acres

of land unsuitable for farming and plants annually a considerable acreage, chiefly with coniferous trees. Conifers do well on sandy soils, and as they grow more quickly than deciduous trees they have a greater economic value. Oaks and elms thrive on clay soils, where

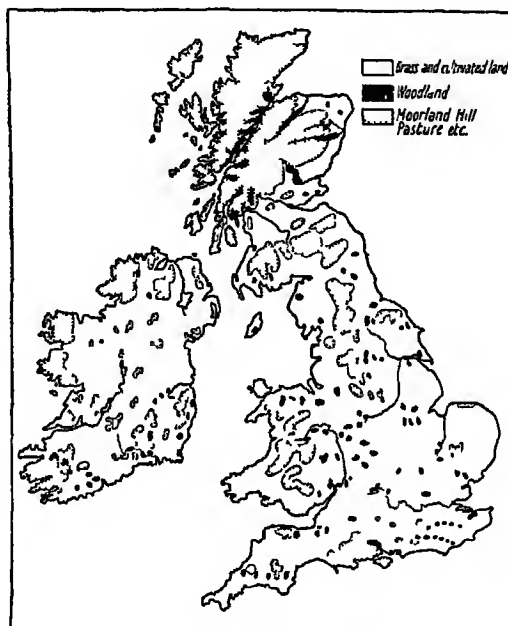

FIG. 81. British Isles: Natural Vegetation.

their long spreading roots collect moisture lying near the surface. Other broad-leaved trees, like beech, are often found on light, shallow soils, such as chalk. The ash is a common tree in limestone districts, such as parts of Derbyshire. Much of the higher ground in Great Britain, and wide tracts in Ireland, consists of moorlands, clad with bracken and heather.

The Weald, the New Forest, the Forest of Dean, parts of Staffordshire and Nottinghamshire, and the Highlands of Scotland (Perthshire, Aberdeenshire and Ross) are among the most thickly wooded regions in Great Britain at the present day.

Agriculture. Up to the first half of the last century Britain was an exporter of foodstuffs. But the Industrial Revolution, which was accompanied by an expanding population and a drift of workers to the towns, so stimulated the demand for agricultural produce that from 1850 onwards foodstuffs began to be imported. Recent years have seen a great increase in home production, but output lags behind demand and at least 75 per cent. of our food is imported. Nevertheless farming is one of our leading industries: out of every 100 workers six gain their living on the land.

The system of farming depends largely on relief, soil, and climate, more particularly rainfall. Hence grass farms predominate in Ireland and the wetter west of Great Britain; arable farms in the drier east; and mixed farms (arable and grass) in the central belt. Yet though a farmer in Central Ireland may concentrate on dairying, and one in the Southern Uplands of Scotland on sheep, it is broadly true to say that the basis of British agriculture is *mixed farming*, the type varying with the district. Many farms are small family concerns on which little outside labour is employed, and where the main consideration is not the output of each worker per hour, but the total amount of produce obtained from the holding.

In the British Isles rather more than half the surface is under pasture of some kind. This may be divided into (i) rough grazing (classed as 'Mountain and Heath'), and devoted mainly to sheep; (ii) permanent pasture, and (iii) temporary pasture.

Cattle. Of the 9,500,000 cattle in Great Britain, many are bred for dairy purposes, owing to the call for liquid milk. The damp climate, and proximity to populous areas, favour dairying in Cheshire, Lancashire, Staffordshire, and Derbyshire, the chief milk-producing counties in Great Britain. Dairy cows are grazed in Essex, owing to the demand of London for milk; and in the Plain of Gwent, the neighbouring South Wales industrial area providing a big market. In Scotland most cattle are reared in the South-West Lowlands and in Fife. In Ireland the majority are grazed on the Central Plain, but, owing to the limited home market, much milk is made into butter, which, with beef cattle, is exported to England.

Sheep. Though there are 28,000,000 sheep in the British Isles, wool is one of the chief imports among raw materials required for textile industries. Sheep are most numerous in upland areas,

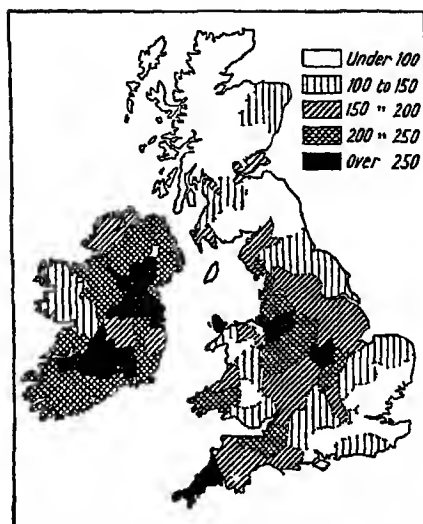

FIG. 82. British Isles. Distribution of Cattle (number per 1,000 acres).

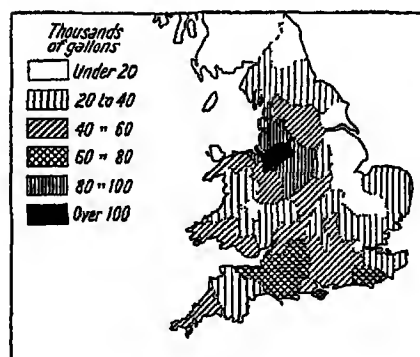

FIG. 83. England and Wales: Milk Production by Counties.

as the Welsh Uplands, the Lake District, the Pennines, and the Southern Uplands of Scotland. When ready for fattening sheep from these areas are sent to lowland pastures. They are also grazed on the North and South Downs, and Romney Marsh.

Pigs. Of the 3,000,000 pigs in the British Isles nearly three-

FIG. 84. British Isles: Distribution of Sheep (number per 1,000 acres).

quarters are found in England and Wales. Pigs consume skim milk and unmarketable potatoes. Thus they are reared on nearly every Irish farm, where potatoes and milk are staple productions. In England large numbers are bred in the milk-producing areas such as Cheshire, and in the potato-growing counties, like Lincolnshire, the Isle of Ely, and Suffolk.

Horses. Owing to the increase of motor vehicles, including tractors, the number of horses in Great Britain declined from 2,000,000 in 1917 to 500,000 in 1958. In Ireland the number has also declined.

Poultry. The introduction of scientific methods of breeding and improved general management have resulted in a great increase in

poultry in recent years and in an increased output of eggs per hen. Poultry are reared in all parts of the British Isles, especially in purely agricultural areas, and near populous districts.

Wheat. Most of the wheat in Great Britain is grown in the east, between the Thames and the Humber, and in the valley of the lower Tweed, and the Lothians. Here the soils, mainly clayey-loams, the sunny summers, the moderate rainfall, and the cold winters, which kill pests in the ground and help to break it up, provide ideal con-

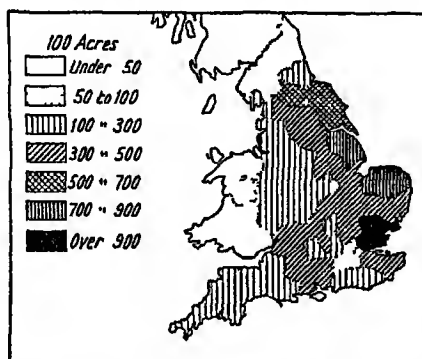

FIG. 85.—England and Wales: Distribution of Wheat by counties, e.g. Essex over 90,000 acres.

ditions for wheat. Moreover, the level land allows the use of machinery for ploughing, sowing, and harvesting.

Barley. The best barley-growing lands are also found in Eastern England, especially on the light chalk and sandy soils of Norfolk and Suffolk. Barley is grown mainly for the production of malt, which is used in the brewing of beer and the distilling of whisky.

Oats are more widely spread than any other cereal, for they thrive equally well in dry areas and in cool wet districts unsuitable for wheat. In England they are grown chiefly in the east; in Scotland in the Eastern Lowlands; and in Ireland in the north-east.

Potatoes are grown in all parts of the British Isles, but some of the heaviest yields are obtained from the alluvial lands of the English Fens.

Other root crops, such as *mangolds*, *turnips*, and *swedes*, are widely distributed, but swedes do best on light soils, in the cooler, damper climate of the north and west; while mangolds thrive in the warmer, drier lands of the Midlands and South-East England. Mangolds are a cattle food, but turnips and swedes are more suitable for sheep. Thus in Cheshire, where there are more cattle than sheep, there is a larger acreage of mangolds than, for example, in Northumberland, where there are more sheep than cattle.

Sugar-beet. The acreage under this crop rose from 22,000 acres in 1924 to 430,000 acres in 1957, when the output was 4,500,000 tons. The main producing counties are Norfolk, Suffolk, the Isle of Ely, Lincolnshire, and Shropshire. The sugar-refineries are situated at central points in these areas.

Hops do well on mixed soils. The principal hop-growing districts are Kent, Sussex, Herefordshire and Worcestershire.

Fruit. Kent is the leading fruit-growing area in the British Isles, producing apples and plums as well as soft fruits such as gooseberries, raspberries, and strawberries. Parts of Cambridgeshire, Essex, the Vale of Evesham, Cheshire, Yorkshire, and the Carse of Gowrie in Scotland are other noted fruit-producing areas. Herefordshire and Gloucestershire, Devon and Somerset are celebrated for their cider apples.

Market Gardening. Throughout the British Isles market gardening is carried on in the proximity of cities and large towns, which provide a market for vegetable produce. But Cornwall, Devon, and the Scilly Isles, though remote from large centres of population, are, on account of their favourable climate, famous for their early vegetables and flowers; while East Anglia and the Fen districts are one of our most important vegetable-growing areas.

Fisheries. The shallow seas, notably the North Sea, covering the continental shelf around the British Isles, are rich in green plants and tiny organisms, called plankton, which abound in the upper layers of the waters. These, together with debris brought down by rivers, provide valuable food for fish. Fishing is an important industry in the United Kingdom, which is the chief country in Europe both for the import and export of fish.

Demersal or deep-sea fish, which live on or near the bottom of the sea, include haddock, sole, plaice, cod, turbot, and halibut. Among

7. TRADITIONAL OCCUPATIONS

(Above) When the hops have been dried in these Kentish oast-houses they are sent to the hop market ready for the breweries. At the beginning of September whole families migrate from London to help gather the hops which may be seen on the right (see p. 144). (Below) Scottish fishermen are packing herrings into boxes ready to be dispatched by fast 'fish-trains'. Some of the herrings are cured for bloaters and kippers. Others are salted and

8. THE WEST COUNTRY

(Above) This stretch of coast at Boscastle, with the rock stack on the right, is typical of Cornwall and Devon. Fishing is naturally a traditional occupation, but the mild climate of South-west England, like that of the Scilly Islands (below), favours the production of early flowers, fruits, and vegetables which find a ready market in London and other populous centres. The men we see here are gathering daffodils (see p. 139).

the chief *pelagic*, or surface-swimming, fish found in the seas around the British Isles are herrings, mackerel, and pilchards. Deep-sea

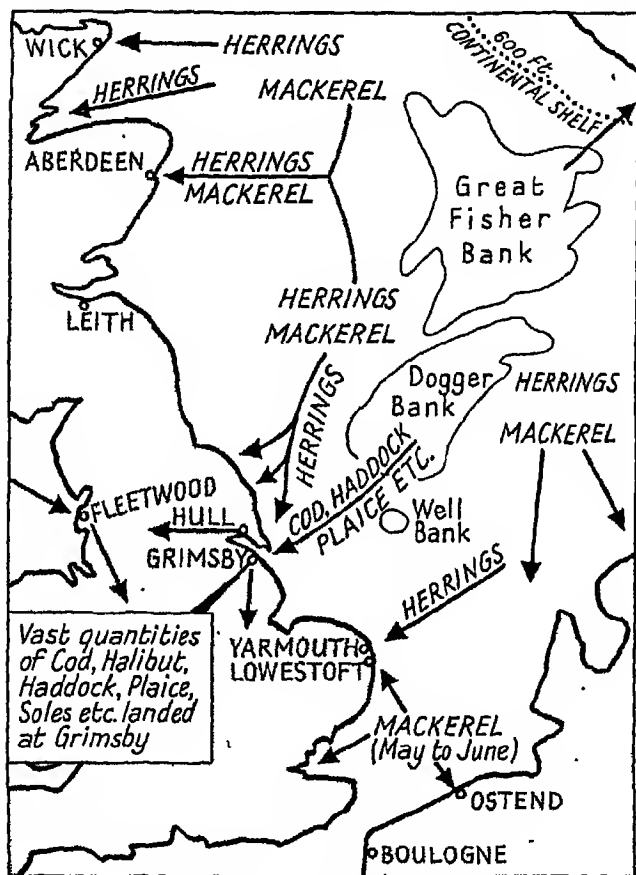

FIG. 86.—North Sea Fishing Grounds.

fish are caught by trawlers; surface-swimming fish by drifters. Trawlers, which go much farther afield than drifters, supply some 85 per cent. of the fish consumed in Britain.

As the North Sea is our leading fishing-ground, the chief fishing-ports are found on the east coast of Great Britain. Grimsby and Hull, the two most important, send trawlers to the Dogger, Well, and Great Fisher Banks in the North Sea; to the Irish Sea and the English Channel, and to waters round the Faroes and Iceland. From Fleetwood and Milford Haven trawlers go to fish for hake off the north of Ireland and the west of Scotland, and visit the North Atlantic grounds. Of the many fishing-ports in South-West England, Plymouth and Brixham deal mainly with sole, plaice, and whiting.

The North Sea abounds in herrings. Herring fishing begins off the west coast of Scotland in May, when Stornoway, in the Outer Hebrides, is the centre of the drifters. From July until September fish are caught in succession off Lerwick, Wick, Fraserburgh, Peterhead, and Aberdeen. In September the fish appear off the Yorkshire coast; then from October to December Yarmouth, the premier British herring port, and her neighbour Lowestoft become centres of the fishery. The season finishes towards the end of December, when many vessels depart for the waters round Cornwall, Devon, and Ireland, where mackerel fishing is carried on from February to May.

In an average year 600,000 tons of fish are landed in Great Britain, one-third in Scotland, the rest in England. Cod, haddock, and herring account for almost 70 per cent. of the catches.

Minerals. *Coal.* The British Isles produce 14 per cent. of the world's coal, their annual output being exceeded only by that of the United States and the U.S.S.R. It is coal that provides the energy that drives the machinery in our mills, factories, and ships, it yields fuel for blast furnaces, gas-works, and thermal stations where electricity is generated. It is also an important export. No other country possesses so many kinds of coal as Great Britain, and from one field or another can be obtained coal for every domestic, commercial, and industrial purpose.

We may divide British coal-fields into two groups: (i) the inland fields, providing coal mainly for home industries and domestic purposes; and (ii) those lying near the coast where the coal is mined chiefly for sale outside the area.

The *inland group* includes the *Lanark coal-field*, from which nearly half the coal in Scotland is obtained; the *York-Derby-Nottingham*

field, whose output is the largest in the British Isles, and from which some coal is also exported via the Humber ports; the *South Lancashire* field; the *North and South Staffordshire* fields; the *North Wales*

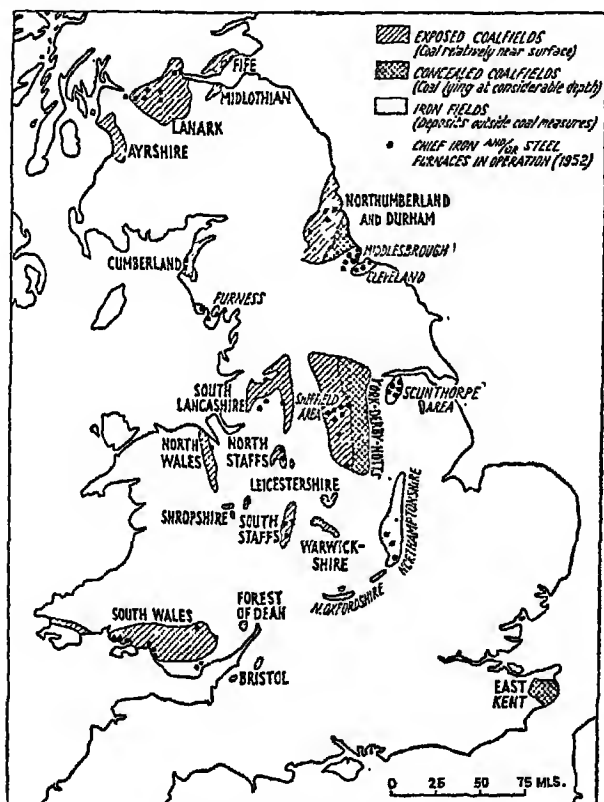

FIG. 87.—British Isles: Coal-fields.

field; the Midland fields of *Leicestershire*, and *East Warwickshire*; and the small *Forest of Dean* and *Bristol* fields.

The *exporting group* includes the *Ayrshire*, *Fifeshire*, and *Lothian* fields of the Midland Valley of Scotland; the small *Whitehaven* field; the *Northumberland and Durham* field; and the great *South*

Wales coal basin, whose anthracite and smokeless coal are in much demand throughout the world.

Iron Ore. To-day, owing to the exhaustion of supplies, little of the iron ore mined in Britain comes from the coal-fields; yet in most fields ores were originally found close to both coal and limestone, the latter used as a flux in smelting. Hence the coal-fields became iron producing, and, later on, steel producing areas. The chief deposits of iron ore, now worked at varying distances from the coal-fields, are found in (i) the *Cleveland* district of Yorkshire; (ii) the *Furness* district of Lancashire; and (iii) along a broken belt yielding low-grade ores, which extends through *Lincolnshire* and *Northamptonshire* into *North Oxfordshire* (see p. 131). Great Britain imports nearly half her iron ore, mainly from Northern Spain, Sweden, Algeria, Greece, and Canada (Newfoundland).

Other minerals include *lead*, mined in the district east of Snowdonia, Cornwall, and the Isle of Man. *Tin* and *copper* have been mined in Cornwall from early times, but the present output is small.

Non-metallic minerals. Mines are only found in certain districts in the British Isles: more common are the quarries, gravel and clay pits from which most of our non-metallic minerals are obtained. Sedimentary rocks are easily quarried and worked, and of these the majority of sandstones, grits, and limestones form good building materials. Sandstone is used as a building stone in areas where it is found, such as the New Red Sandstone Plain of the Midlands, and the Malvern Hills (Old Red Sandstone). In limestone districts, like the Cotswolds, the churches and older houses are usually built of local stone. Besides its use for smelting iron ore, limestone is used in making cement, and when 'roasted' for fertilizing the land. Granite and other igneous rocks are difficult to work. Owing to their weight they are only used for ordinary building purposes in areas where they are quarried, e.g. round Aberdeen and Dartmoor. Granite and basalt, another igneous rock, are used in road-making. In the course of ages granite may decompose to form kaolin, or china clay, used for making pottery, and obtained mainly from Cornwall and Devon. Slate, a metamorphic rock, is a useful roofing material. There are large quarries at Llanberis, Bethesda, and Penrhyn in North Wales.

Rich deposits of salt in Cheshire and the south-east of County

Durham furnish an essential raw material for heavy chemical industries, located respectively on Merseyside and Tees-side.

Electricity and Nuclear Power. Most of Britain's electricity comes from power-stations using coal; some from hydro-electric plants; and some from nuclear-power stations using uranium.

FIG. 88.

FIG. 89.

Nuclear-power stations must be carefully sited. Since vast quantities of water are needed, most nuclear power stations are built near the coast, or by large estuaries, or lakes. Because of their enormous weight they can only be erected where the bedrock provides a firm foundation; and though they are placed in open country, yet, from an economic point of view, they should be relatively near a populous area. Nuclear-power stations include those at Calder Hall on the edge of the Lake District; Berkeley, Oldbury, and Hinkley Point on the Severn estuary; Dungeness, Kent; Bradwell and Sizewell on the coast of East Anglia, and Hunterston, Ayrshire.

Overseas Trade. Fig. 88 shows that our chief imports are food-stuffs, and raw materials needed for manufactures, and petroleum. Our leading exports (Fig. 89) are manufactured goods, including machinery; motor vehicles, ships, and aircraft; chemicals (fertilizers, drugs, plastics, salt etc.); and refined petroleum

and petro-chemical products, such as synthetic fibres, e.g. terylene.

Our imports are of far greater value than our exports. This adverse balance is partly corrected by our *invisible exports*, i.e.

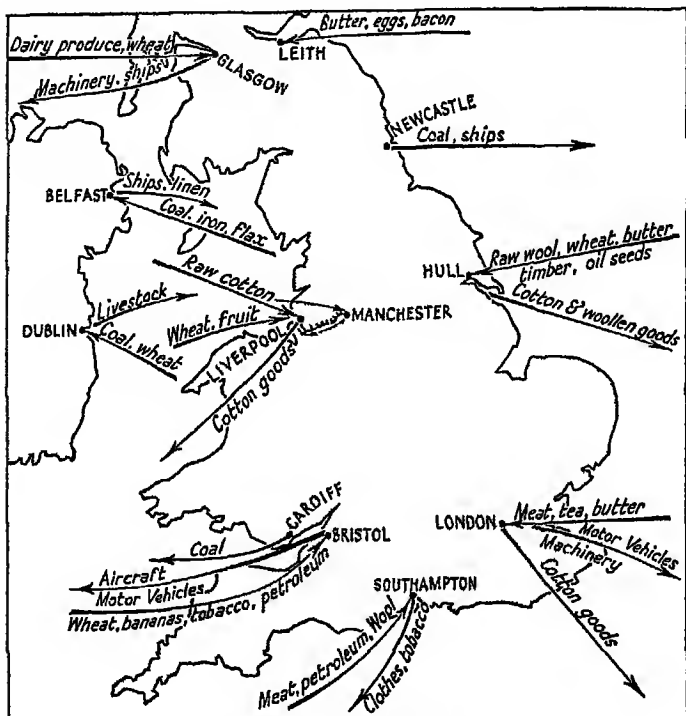

FIG. 90.—British Isles: Trade.

profits derived from our shipping and air lines, from British capital invested overseas, and from banking and insurance transactions. Another source of our national income is the money spent by the many thousands of tourists, who each year flock to the British Isles from countries far and near.

Fig. 92 shows that we import most goods from the United States, Australia, and Canada, followed by India and New Zealand. From Fig. 92 we see also that four of our ten best customers are members of the Commonwealth.

Population. Less than two centuries ago, when farming was still the chief occupation in Britain, the most thickly peopled region was

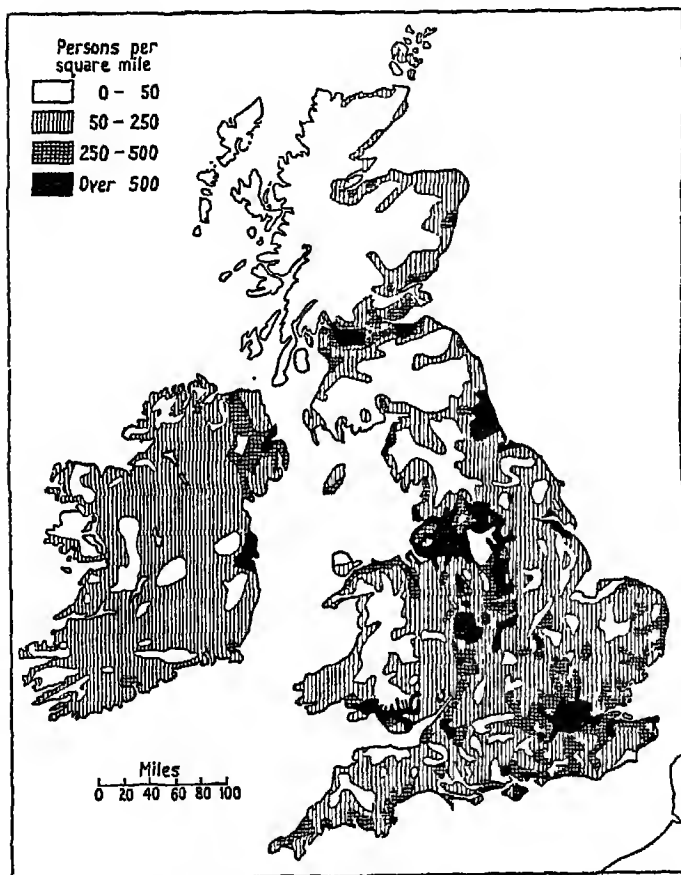

FIG. 91.—British Isles: Distribution of Population per square mile.

the fertile agricultural belt extending from the Bristol Channel and the lower Severn through the Thames valley into Kent, and north-east into East Anglia. The Industrial Revolution started a movement

of workers from the rural areas to the growing towns on the coal-fields: in England from the South and East to the North-West Midlands and the North; in Wales towards the South Wales Coal Basin; in Scotland from the Highlands and the Southern Uplands to the Midland Valley. This exodus from rural to urban areas has continued right up to the present day.

FIG. 92.

At the 1961 census the United Kingdom had a population of 52,673,000, of whom approximately 46,000,000 lived in England and Wales, 5,178,000 in Scotland, and 1,423,000 in Northern Ireland. A comparison between the population map and that of the coal-fields (Fig. 87) shows that the most thickly peopled areas in Great Britain are (a) the industrial districts on the coal-fields, and (b) Greater London and the surrounding region. In recent years there has been a steady movement of population to the latter region, due largely to the development of manufacturing consequent on the increased use of electricity. Associated with it, not only in London but in other large cities, there has been a movement of industry and population from congested central districts to the suburbs and the surrounding country. And since the last war there have also been established a number of new towns, such as Crawley, Sussex, Harlow, Essex, and Stevenage and Hemel Hempstead, both in Hertfordshire.

The most thinly populated regions in Great Britain are the Highlands of Scotland, the Welsh Uplands, and the Pennine moorlands. Except for the Belfast area, Northern Ireland is rather sparsely peopled, mainly because it is an agricultural country.

Note. The diagrams on this page, and similar diagrams in this book, are based on recent three years' averages.

EXERCISES

1. Illustrating your answer by a sketch-map, describe the physical features of the English Plain.
2. In what parts of England are many of the older buildings constructed of local stone? Name the type of stone used in the localities you mention.
3. Compare and contrast the physical features of Scotland and Ireland.
4. The annual rainfall at Valencia is 55·7 inches, and at Nottingham 22·6 inches. Account for the difference in rainfall between these two places.
5. (a) What type of climate has the British Isles? Name *one* country in the Southern Hemisphere with a similar type of climate. (b) Which parts of the British Isles are (i) warmest in summer; (ii) coldest in winter; (iii) coolest in summer; (iv) mildest in winter; (v) most equable throughout the year; (vi) have the greatest range of temperature; (vii) have the least range of temperature? In each case state briefly the reasons for your answer.
6. What kind of weather would you expect in July when an anti-cyclone was centred over the British Isles?
7. How do you account for the following facts: (a) the leading milk-producing counties in England are Cheshire, Lancashire, Staffordshire, and Derbyshire; (b) Essex, Norfolk, Lincolnshire (Lindsey), and the East Riding of Yorkshire are the chief wheat-growing counties in the British Isles; (c) the district round London and also the Scilly Isles grow much vegetable produce; (d) pigs are widely reared both on the Irish Plain and in Lincolnshire?
8. Explain why (a) two hundred years ago most people in England lived in the South and East; (b) now most people live in the North; and (c) at present the population of the South is increasing more rapidly than that of the North.
9. Choose *three* fishing ports in Great Britain, one on the east coast, one on the south coast, and one on the west coast, and explain the reasons for the situation and importance of each.

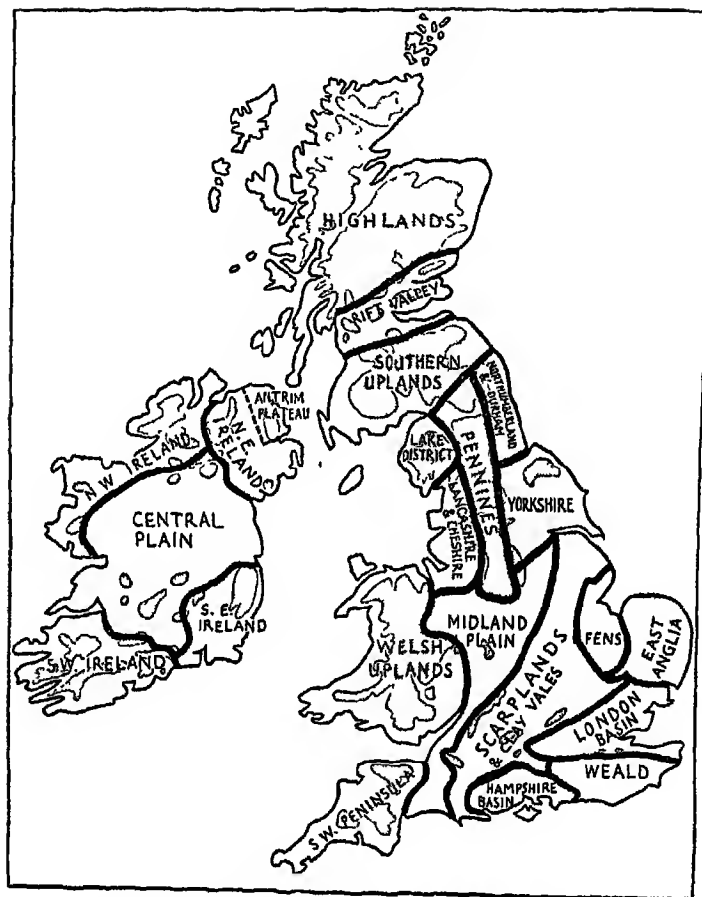

FIG. 93.—British Isles: Chief Natural Regions.

A Natural Region is one that exhibits throughout its area certain geographical uniformities as regards physical features, rock structure, soils, climate, and the resultant products and human activities.

CHAPTER XII

REGIONS OF THE BRITISH ISLES

GREAT BRITAIN

South-west England. South-west England with its genial climate, indented coasts, heather-clad moors, and verdant valleys, has a charm peculiarly its own. Devon and Cornwall differ somewhat in structure and relief from Somerset, but Somerset shows such marked resemblances to its neighbours that to these three counties the term 'The West Country' is applied.

The peninsula of Cornwall and Devon consists mainly of sandstones and slates through which have been thrust up granite bosses, from which veins containing tin, copper, and other ores extend into the surrounding country. The chief of these granite masses are Dartmoor and Bodmin Moor, separated by the valley of the Tamar. In North Devon, Exmoor, whose cliffs rise a thousand feet above the Bristol Channel, is composed of hard sandstones, limestones, and slates. On the east this upland is continued by the Quantocks into Somerset. Bleak, rain-drenched plateaus, like Dartmoor, with their thin infertile soils, are quite unsuited for cultivation. There are few trees, and large stretches are covered with coarse grass, interspersed with bogs. Small ponies and deer roam over the moors, while from spring to autumn cattle and sheep graze on the rough pastures, returning to the valleys for winter.

The sparsely peopled uplands present a great contrast to sheltered lowlands like the Plain of Devon, drained south by the Exe and north-west by the Taw and the Torridge to Barnstaple Bay. The New Red Sandstone of the Plain weathers to form fertile loam soils which furnish orchard lands and pastures for the famous Red Devon cattle, bred primarily for beef. The mild climate of the southward-facing valleys favours the production of early vegetables, fruits, and flowers for London and other markets.

For centuries the peninsula was noted for its tin and copper mines found on the margins of the granite uplands. But mining is no longer important, and adventurous Cornish miners have migrated to all parts of the world. The decline in mining is due partly to the exhaustion of the more accessible veins, but chiefly to the competition

of more cheaply worked ores from overseas. Cornwall and Devon still produce much *kaolin*. Formed by the decomposition of granite, it occurs in 'pockets', or hollows, on the borders of the granite bosses. Much is dug round St. Austell, Bovey Tracey, and Lee Moor (near Plymouth), whence it is exported through Fowey,

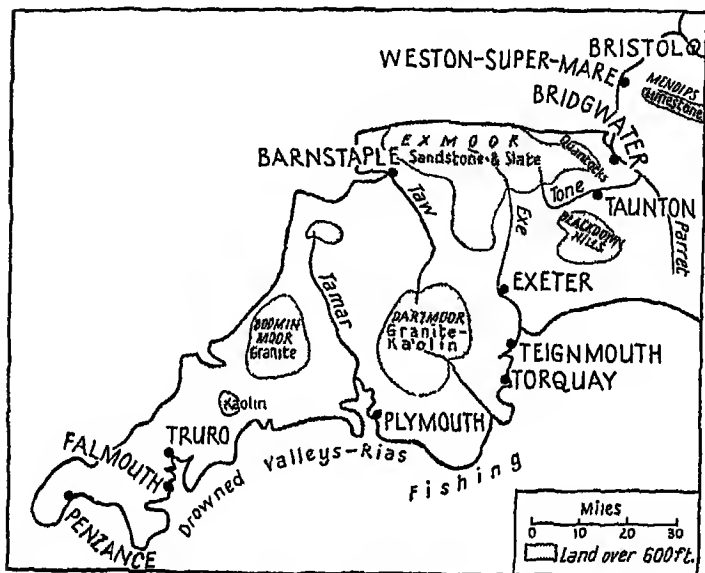

FIG. 94.—South-west England.

Teignmouth, and Plymouth to the potteries of Stoke-on-Trent and Worcester, and to Lancashire where it is used to give weight and finish to cotton goods. In Somerset there are two small coal-fields, one near Bristol and another north of the Mendips.

The coasts of Cornwall and Devon, with their bays, rugged headlands, and estuaries, are famed for their beauty, which attracts thousands of visitors each year. From Falmouth to Exeter the 'drowned' ends of the valleys form rias, some of which, like Falmouth and Plymouth Sounds, are magnificent harbours. Most of the ports are small. St. Ives, Falmouth, Brixham, and Penzance are fishing centres. Penzance is the port for the *Scilly Islands*, which are noted

for their early vegetable produce. Torquay and Ilfracombe are sea-side resorts. The city of *Plymouth*, comprising Plymouth, Devonport, and Stonehouse, grouped round Plymouth Sound, is a naval port with repair and shipbuilding yards, and a route and market centre. From Plymouth the Southern Region Railway runs north and the Western Region line south of Dartmoor, to *Exeter*, a

FIG. 95.—The Site of Bristol.

cathedral city whence the route runs up the Exe valley, and thence to Taunton, on the Tone, the county town of Somerset.

The *Plain of Somerset*, drained by the Parret to the flat coast here margining the Bristol Channel, stretches from the Quantock and Blackdown Hills to the Mendips. Like those of Devon, the valleys opening to the plain are noted for cider-apple orchards, while the low-lying meadow lands are devoted to dairying. Milk is sent to Bristol and London, but some is made into cheese taking its name from Cheddar, a picturesque village at the foot of the famous Cheddar Gorge, through the Mendip Hills. Weston-super-Mare is a popular sea-side resort; Bath, on the Avon, has for centuries been a noted spa. Vessels of moderate size can ascend the Avon to *Bristol* (440,000), but larger steamers anchor at Avonmouth or Portishead. The colonial trade of Bristol dates from the days of the slave trade, when her ships took goods to West Africa, thence carried slaves

to the West Indies, returning with cane-sugar to Bristol. To-day sugar, cacao, tobacco, and wood-pulp supply raw materials for local manufactures. Other imports are grain and petroleum.

The Hampshire Basin. Enclosed by the semicircle of chalk uplands formed by the Purbeck, Western, and Hampshire Downs is a *downfold* where the chalk has been covered with gravels, sands, and

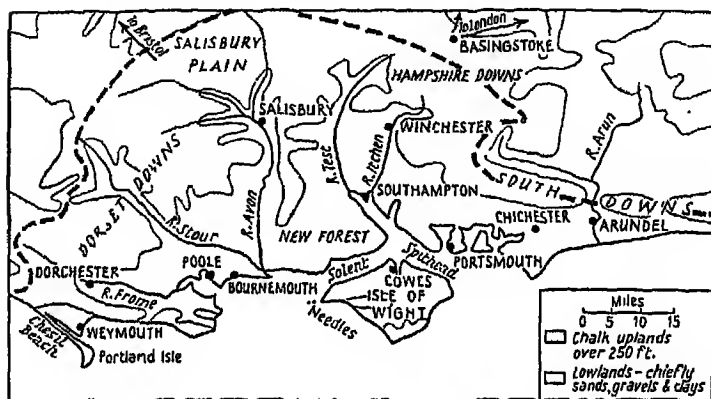

FIG. 96.—The Hampshire Basin.

clays. This region is the Hampshire Basin, in which we may include the *Isle of Wight*. Farming is the chief occupation. Sheep are grazed on the Downs, and dairy cattle on the lowlands. The New Forest covers much of the sandy district west of Southampton Water. *Portsmouth* is a naval base. The four tides a day, which enable vessels to dock at any time, have helped to make *Southampton* the premier passenger port in the British Isles, and an outpost for London. Of a number of routes converging on the town, one runs up the Itchen valley to *Winchester*, once the capital of England, the other through Salisbury to Bristol. *Bournemouth* and other sea-side towns, including a number in the Isle of Wight, are popular resorts. So, too, is *Weymouth* (Dorset), a packet-station for the Channel Islands.

South-east England. From the Hampshire Downs the *North* and *South Downs* run east, enclosing within their inward-facing

escarpments the Weald. At the foot of the scarps scattered farm-houses and villages tell of springs occurring where water, after filtering through the porous chalk, comes to the surface at its junction with the impervious clay. The Downs are the remains of a

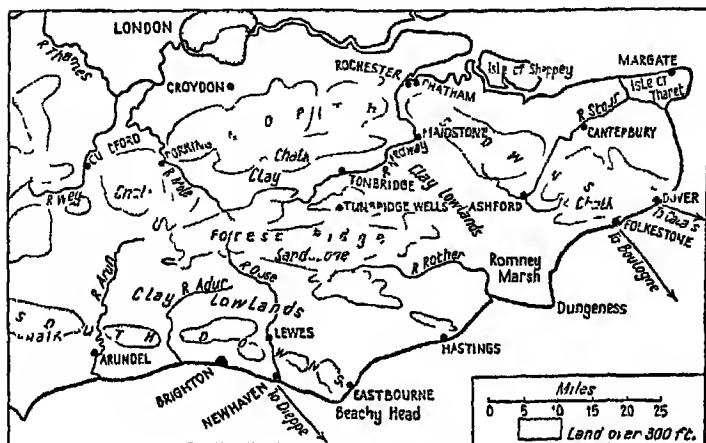

FIG. 97.—South-east England.

FIG. 98.—Generalized Section across South-east England from N. to S.

dome-like *upfold* of which the central portion has been worn away, exposing the underlying clays and sandstones of the present Weald. In the centre of the shallow basin forming the Weald, hard resistant sandstones compose the Forest Ridge (see Fig. 98), which runs parallel to the Downs. Its woodlands remind us that at one time the Weald was thickly forested, its trees yielding timber for ships and charcoal for smelting local iron ore. The development of the

East Kent Coal-field (where coal is mined beneath iron-yielding rocks) has led to some revival of the iron industry.

Before the original chalk dome was worn away, streams ran north and south, cutting their valleys into the chalk. The gaps in the North and South Downs, the remains of these former valleys, now provide sites for towns and are utilized by roads and railways. At gaps in the South Downs stand Arundel, on the Arun, and Lewes, the county town of Sussex, on the Ouse. Among the 'gap-towns' in the North Downs are Guildford, the county town of Surrey, on the Wey; Maidstone, the county town of Kent, at the southern end of the Medway gap, and Rochester-Chatham at its northern end; and historic Canterbury commanding the Stour gap. Rochester and Chatham, with Gillingham, form the Medway ports. They export cement (river mud and chalk), and import oil, coal, iron, and wood-pulp for paper making, e.g. at Dartford and Sittingbourne.

Many coastal towns, like Bognor Regis, Worthing, Brighton, Eastbourne, Hastings, Margate, and Ramsgate, are pleasure resorts. The packet stations of Dover, Folkestone, and Newhaven remind us of the close connexion of South-east England with the Continent.

The agricultural products are varied. On the chalk Downs sheep are grazed, some wheat is grown, while dairy cattle, pastured in the clay vales, provide milk for London, and other populous centres. The relative dryness, absence of cloud, and high percentage of sunshine, coupled with the mixed soils, favour the growing of fruit and hops, for which East Kent is specially noted. The proximity of London accounts in large measure for the chain of market-gardens stretching from the lower Medway westward along the Thames estuary. The life of South-east England is intimately bound up with that of the metropolis, for not only does much of its produce find a market there, but many people who work in London live in the Weald, on the North Downs, or at places along the coast, connected by fast electric train services with the capital.

The Central Scarplands. From Dorset to Yorkshire the limestone and chalk ridges, with the intervening clay vales, which form the *Scarplands* are a striking feature of the English Plain. This central region is intimately bound up with adjacent areas. Indeed the Vale of Pickering, between the limestone North York Moors and the chalk Yorkshire Wolds, is more conveniently studied with the

9. THE PORT OF LONDON: THE ROYAL DOCKS

On the left may be seen the *King George V Dock*: on the right are the *Royal Albert Dock* and (background) the *Royal Victoria Dock*, which together form the largest sheet of enclosed dock water in the world. The warehouses alongside the quays are filled with meat, grain, tobacco, and other commodities. With the exception of the *Surrey Commercial Docks*, all the docks along the Thames lie on the left bank. Each has its own special trade. For instance, the *Surrey Commercial Docks* import much timber, and the *East and West India Docks* deal with produce from West Africa, e.g. palm-oil and cacao. Thames barges are widely used for conveying goods from ships to the warehouses along other parts of the Port of London, and for transporting produce from incoming to outward-bound vessels.

10. SLATE, POTTERY, AND COAL

(Above) A slate quarry in North Wales with the Snowdon Range in the distance (see p. 155).

(Below left) A thrower at work on the potter's wheel in a famous Stoke-on-Trent pottery. Much of the kaolin, or china clay, is obtained from Cornwall and Devon. (Below right) Miners in a Tyneside mine being carried in coal tubs to the seams (see p. 166).

grown both in the plains and on the uplands, where the fields are often strewn with stones. Much dairying is carried on in the clay vales; such towns as Aylesbury, at the northern end of the Chiltern Gap and a focus of other routes across the lowlands, and Banbury are leading centres for the collection and distribution of milk. The latter town has also one of the largest cattle markets in the British Isles. Local hides still provide raw material for boot factories at *Northampton* and Kettering, but much leather is now imported from the grasslands of Argentina and Australia. Sheep yield wool which is made into blankets at Witney, and cloth at Bradford-on-Avon, Westbury (Wilts), and Stroud, in a transverse valley leading through the Cotswolds.

The Evenlode and Cherwell valleys converge on that of the Thames at *Oxford*, which, like many university towns, is a printing and publishing centre, while industry is further represented by the huge motor-works at Cowley on the outskirts of the city. Its sister university town of *Cambridge* stands on the margin of the Fens. *Bedford*, on the Ouse, is noted for its schools. The cathedral city of *Lincoln*, in the gap cut by the Witham through Lincoln Edge, manufactures agricultural and excavating machinery.

The Jurassic Limestones yield iron ore smelted at Scunthorpe, Wellingborough, Corby, and Kettering. In the limestone districts the churches and older houses are built of local stone; in the chalk lands partly of flint; but in the clay vales both older and newer dwellings are constructed of brick.

The London Basin. The London Basin is a shallow trough formed by a *downfold* in the chalk upon which has been deposited sands, gravels, and clays. It is a triangular depression extending from the Vale of Kennet, along both sides of the Thames, and widening towards the North Sea. The Basin is flanked by the chalk *upfolds* of the Chilterns and East Anglian Heights on the north-west, and by the North Downs on the south.

Shortly after entering the Basin through the Goring Gap, between the White Horse Hills and the Chilterns, the Thames receives the Kennet, the united stream following the direction of the latter river. *Reading*, at the confluence of the two, is the second largest town in the Basin. Biscuits were originally made here because much wheat was grown in the surrounding district. This is no longer the case,

but the persistence of the industry, to which must be added the manufacture of other foodstuffs, provides an interesting example of *geographic inertia*—the tendency on the part of established industries to remain where they are long after conditions have changed.

The beech woods of the Chilterns still provide part of the timber for the chair factories at *High Wycombe*, though much material is now imported from Sweden. Dairying, market gardening, fruit

FIG. 100.—The London Basin.

growing, and poultry farming are among the leading rural occupations both in the Thames valley and Essex, where to some extent they have replaced wheat growing. Essex is still, however, the leading county in Britain for the production of wheat.

Essex and the Thames valley are residential districts for people working in London. In recent years the region around the capital has been transformed by the establishment of many industries, stimulated by cheap electric power. Among them are paper-making (pure water) at Watford and St. Albans, engineering at Chelmsford, Braintree, Colchester, and Luton (also famed for hats); the making of motor vehicles at Dagenham, and linoleum at Slough.

London. The life of the London Basin, and indeed of the whole of South-Eastern England, is intimately bound up with that of the metropolis. The city arose at the lowest spot where the Thames

could be bridged. At this point it grew up on the left bank of the river on firm ground which rose above the marshes to west and east. Here routes coming from the Continent via Dover, and confined between the North Downs and the right bank of the Thames, were able to cross the river, after which they spread out fan-like in all directions. Nearly all the ways radiating from London pass through gaps in the surrounding chalk hills, whose position (see Figs. 100, 101) should be carefully noted. At London land-ways meet seaways converging on the Thames estuary. Ships unload cargoes at wharves along the river, and direct into lighters for distribution, but the majority use the huge dock system. All the docks, except the Surrey Commercial Docks, lie on the left bank of the Thames. The *Port of London* handles one-third of the imports and one-quarter of the exports of the United Kingdom.

London has excellent road and rail services, including the Underground system, whose construction was facilitated by the underlying clay. The chief airport is London Airport.

The industries of London, like those of Paris or Berlin, are too numerous to enumerate, but among them may be mentioned the manufacture of soap, furniture, glass, matches, and chemical products, and it should be noted that different districts specialize in different commodities. In recent years many light industries have moved from inner London to the outer belt, where there is more room for expansion. London is a great wool, tea, and rubber market. It is the world's chief banking centre, and its second largest city. Its population of $8\frac{1}{2}$ millions is double that of Birmingham, Glasgow, Manchester, and Liverpool combined. London is the seat of the British Government, the capital of England, and the leading city of that unique association of territories and peoples which forms the Commonwealth.

East Anglia. The name of East Anglia is derived from the Angles who, sailing up the estuaries of the Orwell and the Yare, occupied the districts that are now Norfolk and Suffolk. Here and there the level surface of these counties is broken by low hills, but even the East Anglian Heights do not exceed 300 feet. Much of this region is covered with boulder clay and glacial sands and gravels. These form a fertile soil which, coupled with the climate, makes East Anglia one of the best arable farming areas in the country. There is

FIG. 101.—The Site of London in detail.

FIG. 102.—Simplified Geological Map of London. Scale · 1 inch 3 miles.

former swamps the Witham, the Welland, the Nen, and the Ouse flow slowly towards the Wash. The whole region is crossed by a network of drainage canals which carry surplus water to the rivers, into which it is lifted by pumping stations. Wheat, potatoes, turnips, and sugar-beet thrive on the rich black earth of the Fens. Fruit is grown to the north of Cambridge, on the Fen margin, and round Wisbech, a river port on the Nen which, like Spalding, is also a centre for vegetables and bulbs.

The land is so flat that even an elevation of a few feet breaks the monotony of the plain. On gentle rises, above flood level, stand villages and towns. Ely was founded on an island in the Fens: on their edge lies Peterborough. Ely, though a cathedral city, is little more than a large village. Peterborough is a town of moderate size with breweries and brickyards. Its future is bright, for when the project, now being undertaken, for canalizing the Nen is completed, it will become an inland port accessible to sea-going 300-ton motor barges. This scheme will also be of great benefit in draining the Fenslands, which, in spite of the many canals that have been constructed, are still subject to disastrous floods.

The Midlands. The undulating plateau comprising the Midlands forms the heart of the English Plain. On the north this region is bounded by the Pennines, on the west by the Welsh Uplands, and on the south-east by the oolitic limestone escarpment. The rocks of the Midland region consist chiefly of New Red Sandstones, marls, the pebble beds which weather to form fertile soils. Above these young rocks rise 'islands' of harder, older rocks whose main importance lies in the fact that they bear the Midland coal-fields. The chief of these upland areas (Fig. 104, p. 153) are: (1) *Charnwood Forest* and the *Leicestershire coal-field* centred on Ashby-de-la-Zouche; (2) the *East Warwickshire coal-field* together with the *Nuneaton Ridge*; (3) the *South Staffordshire coal-field* and the *Clent and Lickey Hills*; and (4) the *Wrekin* and the *Shropshire coal-field*. To these areas must be added (5) the *North Staffordshire coal-field*; and (6) the southern portion of the *York-Derby-Nottingham coal-field*.

Outside the industrial areas, stretches of heather, with scattered larch and pine, still cover the sandy uplands, while trees dot the pastures. At one time considerable quantities of wheat were grown in the Midlands, but now much of the wheat-land has been replaced

by grass, and in all the Midland counties more than half the surface is under pasture. On the damper meadow-lands many dairy cattle are grazed; on drier grass-lands, such as those of Leicestershire, sheep are reared. In such a pastoral region hides are plentiful: tanning is carried on in a number of towns where the water-supply is suitable; boots are manufactured at Stafford and Leicester, and leather goods at Walsall.

The *Vale of Evesham*, drained by the Warwickshire Avon, is noted for its market gardens and orchards. Strung along the river itself are the historic towns of Tewkesbury, Evesham, Stratford, Warwick, and Rugby, the last-named being an important railway centre.

The *Black Country*, a low plateau region in the centre of the Midlands forming the watershed between the basins of the Severn and the Trent, depends for its mineral wealth on the South Staffordshire coal-field. *Birmingham* (1,120,000), on the edge of the Black Country, is the second largest town in England. Since the sixteenth century it has been famed for its iron goods, and to-day it manufactures motor-cars, metal goods and electrical equipment of all descriptions. Many of the Black Country towns specialize in some particular branch of the metal industry: Dudley makes screws, anvils, and vices; and *Wolverhampton* manufactures bicycles and motor-cars as well as wrought iron and tin-plate. *Stourbridge* uses local fire-clay for making fire-bricks required for lining furnaces, and with nearby *Brierley Hill* is famed for its glass.

On the *North Staffordshire coal-field* the Pottery towns (*Stoke*, *Hanley*, *Burslem*, *Longton*, and *Tunstall*), forming the city of *Stoke-on-Trent*, arc, as their name implies, engaged in making pottery. The chief raw materials are kaolin (china clay), bones (used in the manufacture of porcelain), and flints. The china clay comes chiefly from Devonshire; the flints mainly from the Flemish coast and from *Newhaven*; and both materials are brought by sea to *Runcorn*, whence canal barges carry them to the Potteries. The local clay, though providing material for many brick- and tile-yards, is only used in the pottery industry itself for making saggars, the containers in which the ware is placed before being put in the firing ovens.

On the northern edge of the Midlands *Leicester*, *Derby*, and *Nottingham* are important manufacturing centres. *Leicester* is noted for woollen goods and footwear; *Derby* has railway works and makes aeroplane engines and motor-cars; *Nottingham*, an inland

port on the Trent, manufactures hosiery, lace, and tobacco, and is an engineering centre. There are some small oil-fields north-west of Newark-on-Trent. Burton-on-Trent is famed for brewing.

FIG. 104.—The Midlands.

1. Leicestershire; 2. Warwickshire; 3. S. Staffs.;
4. Shropshire; 5. N. Staffs.; 6. Part of York-
Derby-Nottingham.

Coventry makes bicycles, motor-cars, and aircraft, and manufactures rayon.

The four ports serving the Midland area are Liverpool, Hull, Bristol, and Southampton. Liverpool is the chief port for the import and export trade of the Potteries and the Wolverhampton district; the trade of Birmingham and the surrounding district is more equally divided among these four ports.

Wales and its Borders. The Welsh Uplands are margined by a narrow coastal plain on the north, and by the wider lowlands on the south. The Uplands are composed mainly of old rocks, such as sandstones and slates, with a fringe of somewhat younger rocks, like

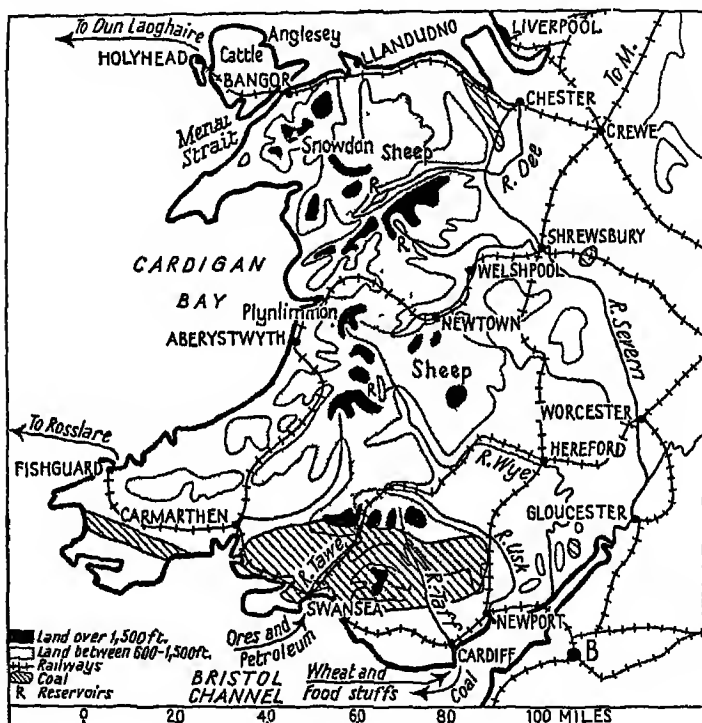

FIG. 105.—Wales and its Borders.

Old Red Sandstone, Carboniferous Limestone, and Coal Measures. Ice has played a great part in moulding the surface of the uplands whose rounded plateaux are separated by valleys deepened by the passage of former glaciers. Here and there more resistant igneous rocks rise as peaks above the surrounding uplands. In the north-west Snowdonia (3,560 feet) is separated by the Menai Strait from the island of Anglesey. There are some hydro-electric power plants near Snowdon. South of the Dee valley rise the Berwyn

Mountains, from whose southern slopes rivers such as the Vyrnwy find their way to the Severn. The Vyrnwy has been dammed to form a lake which is a reservoir for Liverpool, and Birmingham draws its water supply from the Elan Valley, near Rhayader, in Central Wales.

In South Wales the Black Mountains are separated from the Brecon Beacons by the sandstone Vale of Usk which, like the neighbouring valleys of the Taff and the Tawe, forms a route from the Plain of Glamorgan to the South Wales coal basin.

Sheep, bred on the upland pastures, yield mutton and wool. Much wool is sent to Yorkshire, and a little is still manufactured at Newtown, Welshpool, and other towns in the upper Severn valley.

The Severn and the Wye both rise on the slopes of Plynlimmon. The Wye follows a more direct course to the sea. After flowing across the Plain of Hereford, with orchards, pastures, and hop-gardens, it cuts its way through its famous limestone gorge before entering the Bristol Channel.

Shrewsbury stands on high ground almost enclosed by a meander of the Severn. Its site easy of defence, and its command of routes, early made it important, and later led to its development as a railway junction. It is the town most easily reached from all parts of Wales. Through it run railways from South Wales to the north. From the east come lines from the Midlands; to the west a railway runs to Aberystwyth, a sea-side resort and university town on Cardigan Bay.

South of Shrewsbury the Severn flows through a gorge between the South Shropshire Hills and the Wrekin. Then the valley widens, and the river runs through a region of pasture-lands, orchards, and hop-gardens, past Worcester, near the confluence of the Teme and Severn; Tewkesbury, situated where the Warwickshire Avon enters the Severn; and *Gloucester*, at the head of the estuary, standing at the lowest spot where the river is bridged.

The railway from Shrewsbury to Chester runs through Ruabon and Wrexham, mining towns on the small *North Wales coal-field*. From Chester the line to Holyhead (the packet station for Dun Laoghaire (Kingstown)) runs along the narrow plain between the mountains and the sea, where stand watering-places like Llandudno, and historic towns such as Conway and Carnarvon, whose castles remind us of the conquest of Wales by Edward I. Slate, quarried in the neighbourhood of Snowdonia, at Penrhyn and Bethesda, and

granite are exported from small ports along the coast; but the main industry of North Wales is catering for holiday-makers, especially those from Lancashire.

South Wales stands apart from the rest of the country. Here life is bound up with the great coal-field, the third largest in Britain.

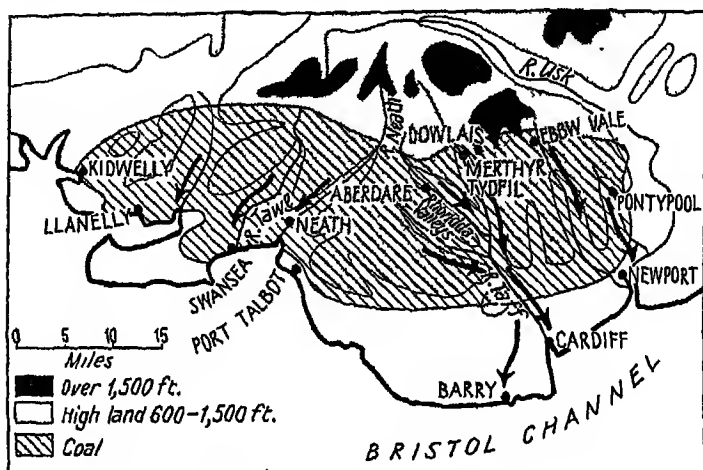

FIG. 106.—The South Wales Coal-field.

The South Wales coal basin extends from Pontypool in Monmouthshire westward for 60 miles to Kidwelly, in Caermarthenshire. The numerous streams have cut through the sandstone to the underlying Coal Measures, and so galleries can be run horizontally into the mines instead of shafts having to be sunk to great depths at much expense. The coal is of high grade and includes steam coal for which the Rhondda valleys are noted. Among the inland towns *Merthyr Tydfil* and *Dowlais* are still engaged in iron-smelting, but as most of the ores are now obtained from abroad, especially from Northern Spain, the newer blast-furnaces are situated at ports like Cardiff and Port Talbot. *Cardiff*, the capital of Wales, is Britain's chief coal-exporting port. *Swansea* is the outlet for the western portion of the coal-field. Formerly tin and copper were sent from Cornwall to be smelted at Swansea, but to-day ore concentrates of tin from Malaya, Bolivia, and Nigeria, copper from Spain and

Chile, and also nickel from Ontario are imported and refined here. Swansea also manufactures tin plate and galvanized-iron sheets and refines oil. There are big tin-plate works near Llanelli. The largest steel works in Europe are situated at Margam. At Port Talbot, close by, is a big strip-mill, where steel is rolled into sheets. These are used by the tin-plate industry, and in the making of goods ranging from motor cars to refrigerators. The *Plain of Glamorgan*, to the south, is devoted mainly to dairying, the bulk of the milk being sent to the industrial area.

The *Western Region* railway, which serves this part of Wales, goes to Fishguard (the packet station for Rosslare), while a branch of this line runs to Milford Haven, on a magnificent harbour, where there is a large oil-refinery, with a jetty able to accommodate two 100,000-ton tankers.

FIG. 107. Simplified Geological Map of the Pennines.

The Pennines. The Pennines stretch from the Tyne Gap southward for 150 miles to the Vale of Trent, decreasing in average altitude from 2,000 feet in the north to 1,000 in the south. The rocks of which they are built are mainly Carboniferous Limestones, Millstone Grits, and Coal Measures (composed of layers of sandstones, shales, coal, and fire-clays) (Fig. 107). Millions of years ago these rocks accumulated on the sea-bed or in big deltas. Later they were bent into upfolds. Subsequent erosion removed from the higher parts of the uplands the Coal Measures, which lay on top, though along the flanks of the Pennines they still remain (Fig. 108).

FIG. 108. Diagrammatic Section across the Pennines.

The Pennines may be divided into three regions.

(1) The *Northern Pennines* consist of a block of table-land cut off by faults in the north, west, and south. On the north the plateau drops to the Tyne Gap; on the south it is margined by the Stainmore

Gap; and on the west it sinks through the magnificent scarp of Cross Fell Edge to the Vale of Eden. On the east a more gradual slope is drained to the North Sea by the South Tyne, Wear, and Tees, which flow across the Northumberland and Durham coal-field. The rocks are chiefly sandstones, with Millstone Grit mantling the higher summits, and spreading along the east and west of the uplands.

(2) The *Central Pennines*, consisting mainly of limestone, extend from Stainmore Gap to the Aire Gap. On the west this wild table-land is bounded by the Dent Fault: on the east it slopes gradually to the plain, but it should be noted that in this part of the Pennines no Coal Measures are found along the flanks of the uplands. From the Central

FIG. 109. The Pennines.

Pennines the Ribble and Lune run west, while on the east numbers of streams flow through verdant dales to the Yorkshire Ouse.

(3) The *Southern Pennines* stretch from the Aire Gap to the Vale of Trent. South of the Aire Gap, where the Millstone Grit moorlands form the narrowest part of the Pennines, the heads of the valleys approach each other, and communications between east and west are easier than in the broader and higher belt farther north. The Southern Pennines are highest in the limestone Peak District, whence streams descend in deep trenched valleys to the Trent. The

Lancashire and North Staffordshire coal-fields lie west and the York-Derby-Nottingham coal-field east of the Southern Pennines.

The regular and heavy rainfall, the elevation, and the nature of the rocks make the Pennine Moorlands unsuited to cultivation. In the limestone districts underground streams, swallow holes, caves, steep valleys, and other land-forms combine to form scenery of the *karst type*. Some of the limestone is dissolved by the streams, causing the water to be 'hard'. The thin soil is covered with short fine grass on which stock are grazed in fields separated by stone walls.

In the Millstone Grit areas layers of peat cover flat-topped hills whose slopes are clad with heather. These moorlands are practically uninhabited, 'but they send down to the bordering lowlands an abundance of soft water which has been an important factor in the development of the textile industries on the flanks'.¹ Rain-drenched and bleak, their waters are collected in reservoirs to supply the manufacturing towns of Lancashire and Yorkshire.

The dale farmers are mainly stock breeders pasturing their animals on the uplands during the summer, and sending cattle to be fattened on the lowlands. Sheep, ten times more numerous than cattle, whose presence did much to establish the woollen industry in Yorkshire, are now bred for meat rather than wool.

Except on the margins of the coal-fields there are no large towns in the Pennines. Hexham and Skipton are focal points in the Tyne and Aire Gaps respectively. Buxton and Matlock are spas.

The Lake District. The Lake District has been aptly compared to an inverted spoon with a broad handle: the dome of the spoon represents the much-denuded Cumbrian mountains, the handle is the high ground of Shap Fell which links this region with the Pennines. Much of the central portion of the Lake District is composed of old sedimentary rocks with granites and slates, both being quarried. This area is margined by lowlands of younger rocks. In the north-west are the Coal Measures of the *Cumberland coal-field* (Maryport, Workington, Whitehaven); while a belt of Carboniferous Limestone, margining older rocks on the south, east, and north-east, contains 'pockets' of high-grade iron ore (smelted over coke from the Northumberland and Durham coal-field) to whose presence is due shipbuilding at *Barrow-in-Furness*. Electricity from *Calder Hall*

¹ *Great Britain: Regional Essays*. Cambridge University Press.

nuclear-power station (see Fig. 110) is fed into the national grid. Water from the lakes, and the sea to absorb the effluent, were two factors that brought nuclear power to Cumberland.

FIG. 110. The Lake District.

The mountain dome of the Lake District culminates in Scafell Pike (3,210 feet) whose sides, seamed with valleys carved deep by former glaciers, are now being eroded by numbers of streams that radiate in all directions. Many of these streams expand into long narrow *mountain ribbon lakes*, partially blocked by deposits of morai-

nic material at their lower ends. Among the chief of these beautiful lakes are Ullswater, drained to the Eden; Thirlmere (one of the reservoirs of Manchester); Derwentwater and Bassenthwaite, separated by an alluvial strip formed by the sediment deposited by rivers checked on entering the once-united lake; Crummock Water (the reservoir of Workington); and Windermere and Coniston draining into Morecambe Bay. The climate of this region is too wet for cereals, but many sheep are grazed on the *fells*, and cattle in the valleys.

The few inland towns are market centres with some small-scale manufactures. Kendal makes woollen goods and boots; Keswick makes pencils, but now relies on imported instead of local graphite. The chief industry is catering for visitors, who flock to the Lake District attracted by its superb scenery.

The *London Midland Region Railway* after leaving Lancaster ascends the Lunc valley, crosses Shap Summit at a height of 1,000 feet, and then descends to the market town of Penrith. The line from Leeds, after traversing the Aire Gap, ascends the upper Ribble valley and crosses to that of the Eden, which it follows to *Carlisle*, a city commanding routes north to Scotland and east through the Tync Gap to Newcastle.

The Cheshire and Lancashire Plain. From the western slopes of the Pennines and the north-eastern slopes of the Welsh Uplands the Cheshire and Lancashire Plain—a prolongation of the main English Plain—stretches to the Irish Sea, to which it is drained by the Dee, Weaver, Mersey, and Ribble. The greater part of this lowland is covered with boulder clay, though, here and there, the underlying red sandstone emerges as low hills. Both the moist climate and the clay soils favour pasture; thus outside the industrial areas dairying, with a market ready to hand, is the leading occupation.

The economic development of this region depends on the *South Lancashire coal-field* extending along the western flanks of the Pennines, an area long famed for its cotton industry, still important but now much reduced in size, partly through competition in overseas markets, and partly owing to the introduction of rayon and other new types of cloth. In 1959 the industry was reorganized. The older mills were closed or put to other uses, and many workers lost their jobs but found employment in other Lancashire industries.

The Lancashire cotton industry superseded an earlier woollen one. As soon as steam replaced running water for power it developed rapidly, and the spinners and weavers easily changed

FIG. 111. The Lancashire Industrial Area.

from wool to cotton. In addition to *coal*, supplies of *pure soft water* and a *damp climate* assisted in localizing the cotton industry in Lancashire. Soft water is required in various processes connected with the manufacture, and for this reason the mills are situated on the margins of the Millstone Grit (sandstone) areas. In a dry climate cotton threads tend to snap in the looms, so it is advantageous for cotton-spinning mills to be situated in regions where the atmosphere is humid, as is the case on the west side of the Pennines.

The chief towns associated with the cotton industry are Manchester and Liverpool. *Manchester* (682,000), standing on a strip of firm ground at a point where many routes meet, has developed from a rural town into the great cotton market of Lancashire. By the construction of the *Manchester Ship Canal*, 35 miles long, this inland city has been made a port, but though much raw cotton is shipped direct to Manchester, more than three times the amount is still unloaded at Liverpool—an interesting example of *geographical inertia*.

Most of the Lancashire cotton towns specialize in some particular branch of the industry. The spinning towns of Stockport, Oldham, Bolton, and Bury are grouped round Manchester. In the more sheltered and drier region of the north, Preston, Burnley, Blackburn, and Darwen are engaged in weaving. After the cloth has been woven it is sent to be bleached, dyed, and 'finished' in South Lancashire. These operations depend on the *chemical industry*, located on and around *Merseyside*. Here towns, such as Widnes and Warrington, are well placed for obtaining salt from Northwich, Middlewich, and Winsford in the Weaver basin; and also for importing by sea other heavy and bulky materials needed by their chemical industries; especially those required for making alkalis used in the preparation of carbonate of soda. Large quantities of the latter product are required by the soap (Warrington) and glass (St. Helens) manufacturers. The chemical industry also supplies materials for silk works at Macclesfield, and tanneries in the Runcorn district, using British and imported hides.

Engineering of various types is carried on. Oldham, Manchester, Blackburn, Bolton, and Bury make textile machinery; Manchester and Salford are also centres for general engineering.

Enormous quantities of paper are required by the many Lancashire industries, and numbers of paper-mills are situated in the Millstone Grit valleys around Manchester. Other industries include the manufacture of bricks and tiles from the shales and clays of the Coal Measures; plastics and rayon; flour-milling at Liverpool (why at a port?), and sugar- and oil-refining.

The early trade of *Liverpool* (768,000) was mainly with the West Indies (cane sugar) and North America. Ferries and railway and road tunnels under the Mersey link Liverpool with Birkenhead, the chief cattle-importing port in the British Isles. Continuous dredging has deepened the entrance to the bottle-shaped estuary through

which the largest liners can pass to anchor at the great floating stage that rises and falls about 20 feet with every tide. London and Liverpool handle between them about half of Britain's overseas trade. Liverpool's imports include cotton, tobacco, and petroleum from the United States; bananas and cane sugar from the West Indies; palm oil, palm kernels, cacao, and copra from West Africa; wheat from Canada, meat from the Argentine, and wool from Australia. Her extensive hinterland furnishes a variety of manufactured goods, many of which furnish return cargoes to primary producing lands. Chief among these exports are motor vehicles, textiles, machinery, chemicals, and pottery.

Most Lancashire towns owe their importance to manufactures, but one large town does not. It is *Blackpool*, most of whose 150,000 inhabitants earn their living directly or indirectly by providing pleasure for crowds of holiday-makers. *Lancaster* stands where the route to Scotland crosses the Lune, but like its sister county town of Chester it cannot compare in size with the industrial centres. *Chester* is a market centre for the pastoral districts of the Cheshire Plain. The railway junction of *Crewe*, to the south-east, owes its importance to its central position in the Midland Gate, through which pass the chief routes from North-West England and North Wales to the south.

Yorkshire. The waters of the Swale, Ure, Nidd, Wharfe, Aire, Calder, and Don, descending from the Pennines, are carried by the Ouse to the Humber estuary. The only left-bank tributary of the Ouse is the Derwent, which once flowed into the North Sea, but during the Ice Age its outlet was blocked by glacial material and the river was diverted to the Ouse.

Outside the Pennine Moorlands Yorkshire falls into three main divisions: (1) the coal-field extending along the flanks of the Pennines, (2) the New Red Sandstone and alluvial plain of the Vale of York, and (3) the Scarplands of the Vale of Pickering, drained by the Derwent.

(1) *The Yorkshire coal-field.* The sheep grazed on the Pennine moorlands, and the abundant supplies of water-power furnished by the upland streams, gave rise to the woollen industry in the Yorkshire dales. The Industrial Revolution, and the consequent development of the coal-field, led to the closing of mills outside the coal area,

and the concentration in the Aire and Calder valleys where plentiful supplies of pure water were available. *Leeds* (482,000), makes ready-made clothes, textile machinery, and soap, and refines oil. It commands a number of routes, including those through the Aire Gap. *Bradford*, to the west, is the great wool market; *Halifax*, in

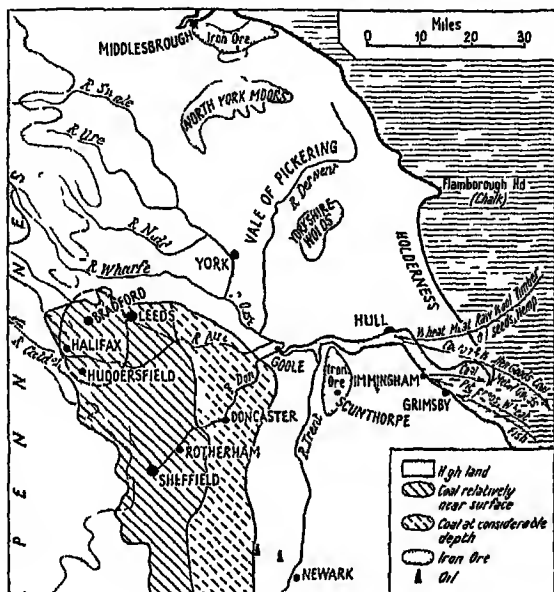

FIG. 112. Yorkshire Industrial Area.

the Calder valley, is noted for carpets; Dewsbury and Batley, lower down the Calder valley, specialize in 'shoddy' (goods made from worn-out fabrics and tailors' cuttings).

In the south of Yorkshire stands *Sheffield* (520,000), on the Don. Local supplies of iron ore, limestone, charcoal and later coal, Millstone Grit, and water-power combined to establish the cutlery industry here; and though conditions have changed, Sheffield still ranks as one of the leading iron and steel manufacturing towns in Britain. Farther down the Don, *Rotherham* is an iron-smelting town, and *Doncaster*, a coal-mining centre, builds locomotives.

(2) and (3) *The Vales of York and Pickering.* The mixed glacial material covering much of the underlying New Red Sandstone of

the Vale of York yields fertile soils on which wheat, barley, oats, and roots are grown. Cattle are grazed on pastures like those of the Vale of Pickering, and sheep on the chalk and limestone hills.

In the centre of the plain stands the cathedral city of *York*. Like other old route towns it is a great railway junction. *Scarborough* is a seaside resort. *Hull*, the leading port in the North-East, on the left bank of the Humber estuary, imports timber, wool, wheat, and oil seeds crushed for vegetable oil. It exports textiles, coal, and metal goods. On the Lincolnshire bank of the Humber stands *Grimsby*, Britain's chief fishing port. Coal is exported through *Goole* and *Immingham*, a port importing timber and iron ore, dispatched to ironworks at *Scunthorpe* to supplement local ores.

Northumberland and Durham. Northumberland and Durham, with the Cleveland District of Yorkshire, constitute a well-defined region stretching from the North Sea across a narrow plain to the Pennine Moorlands. The way from the south comes through the Northallerton Gate and thence across the lowlands to Newcastle, where it divides. One branch continues north to Scotland, passing through the narrow strip between the Cheviots and the sea; the other runs west through the Tyne Gap to Carlisle and the Solway plain. Of the 2,000,000 people who live in this region nearly all dwell on the plain, and few inhabit the moorlands whose pastures form part of a vast sheep-run stretching south into Derbyshire and north to the Southern Uplands of Scotland.

The great *Northumberland and Durham coal-field* stretches from the flanks of the Pennines to the coast, and from Barnard Castle, in the south, to Blyth, a coal-exporting port in the north.

The Tees ports of Middlesbrough and Stockton, with the Hartlepoons to the north, all manufacture steel and build ships. Well placed for receiving coking coal (South-West Durham), iron ore (Cleveland Hills) and limestone (Teesdale etc.), *Middlesbrough* is one of the chief steel-producing centres in Britain. Tees-side is also the seat of heavy chemical industries, whose raw materials include salt, obtained from underground beds nearby, and coal (or imported oil) for fuel. The *Hartlepoons* export coal and import pit-props. *Darlington*, in the Tees valley, builds locomotives. *Sunderland*, on the Wear estuary, exports coal and builds colliers. The Tyneside ports of North and South Shields, Tynemouth, Jarrow, Gateshead,

and Newcastle, depend for their prosperity on coal close to river and sea. Jarrow manufactures chemicals. *Newcastle*, with chemical, engineering, and shipbuilding industries, stands where the East Coast Route, crossing the Tyne at the lowest point where it is bridged, meets that from Carlisle through the Tyne Gap. The

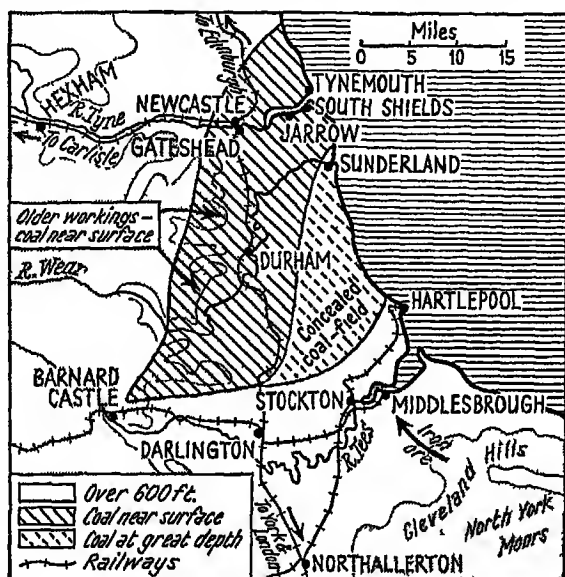

FIG. 113. Northumberland and Durham Coal-field.

Norman castle and cathedral, on a rocky bluff almost encircled by the Wear, are reminders of the importance of *Durham* in the ecclesiastical and military history of the North.

The Southern Uplands of Scotland. The Southern Uplands, consisting of rounded moorlands separated by river valleys, stretch from the Cheviots northward to the Midland Valley, and from the North Sea to the west coast. They descend to lowlands along the shores of the Solway Firth, in the basin of the Tweed, and in Clydesdale which opens to the Midland Valley.

Sheep, bred on the treeless moors, provide wool for factories of

such towns as Hawick on the Teviot, and Galashiels, at the confluence of the Tweed and the Gala. The valleys are a patchwork of woodland, pasture, and ploughland where cereals and root crops are grown. Dairy cattle are grazed in the south-west. The Southern Uplands as a whole are thinly peopled, settlement being almost confined to the valleys and marginal lowlands.

The chief railways from England to Scotland pass through either

FIG. 114. Scotland: The Southern Uplands. Routes between England and Scotland.

Carlisle or Newcastle. Study the following routes with the aid of your atlas, for they provide a key to the configuration of the Southern Uplands. From Carlisle routes run: (1) to Dumfries and thence up Nithsdale to Kilmarnock and Glasgow; (2) to Dumfries and then west to Stranraer, for Larne in Northern Ireland; (3) up Annandale and over Beattock Summit to Carstairs, where one route follows Clydesdale to Glasgow, and the other runs north of the Pentland Hills to Edinburgh; (4) north-east to the Tweed by the valley of the Liddel to Hawick, on the Teviot, and thence to Galashiels and by way of the Gala valley to Edinburgh. The main east-coast route from Newcastle runs to Berwick-on-Tweed and, skirting the eastern end of the Lammermuirs, passes through Dunbar to Edinburgh.

The Midland Valley. This well-defined natural region is a rift valley having an average width of 50 miles. It lies between two roughly parallel faults : one running from Helensburgh, on the Clyde, to Stonehaven marks the southern edge of the Highlands, the other extending from Girvan to Dunbar delineates the northern boundary of the Southern Uplands. When the rift valley was formed, masses of molten rocks reached the surface through volcanoes, or spread out in lava flows over the land. The much-denuded volcanoes still

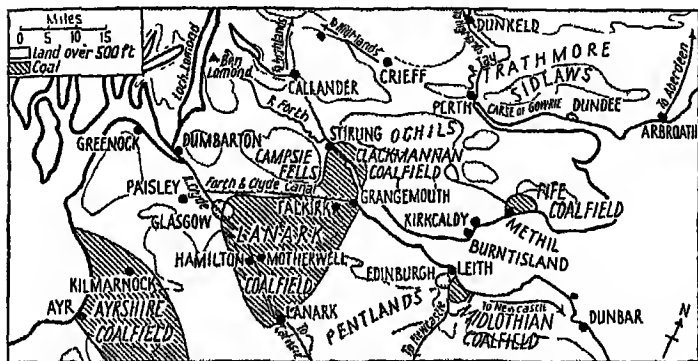

FIG. 115. Scotland: The Midland Valley.

remain as cone-like hills (e.g. Castle Rock, Edinburgh) rising above the sedimentary rocks (Old Red Sandstone and Carboniferous Limestones) that floor the plain. The lava flows formed belts of rounded hills running roughly parallel to the great boundary faults. The more northerly ridges are the Sidlaws, Ochils, Campsie Fells, and Renfrew Heights; the more southerly include the Pentlands and the Lanark Moors. Between the Sidlaws and the edge of the Highlands is the broad Old Red Sandstone Vale of Strathmore, while between the Sidlaws and the Firth of Tay lies the Carsc of Gowrie. The drowned estuaries of the Firths of Tay, Forth, and Clyde which extend into the heart of the Midland Valley provide valuable outlets to the sea.

There are five coal-fields : (1) the Lanark field whose seams emerge across the head of the Forth estuary as the (2) Clackmannan field; (3) the Ayrshire field; and (4) the Midlothian field which extends under the Firth of Forth to reappear as (5) the Fife field.

Of the 5,178,000 people in Scotland three-quarters live in the Midland Valley where, outside the coal areas, farming is the principal occupation. Cattle are bred on the Ayrshire plains, which have a fairly heavy rainfall; sheep on the slopes of the hills. Oats, potatoes, and other root crops are widely grown, but barley and wheat are confined to the drier, sunny east. There are a number of small fishing and tourist centres around the coast.

The Lanark coal-field and the Lower Clyde. The Lanark field stretches from Glasgow south-east to Lanark, and eastward to the north side of the Forth estuary. Grangemouth, at the eastern end of the Forth and Clyde Canal, has a big oil-refinery. In addition to coal blackband iron-stone occurs in the shales of the Coal Measures, and, though at the present time little is mined (most of the iron ore being imported), it was the presence of this iron-stone and coal, in proximity to the Clyde, that caused that river to become one of the leading shipbuilding areas in the world. At inland centres on the coal-field, such as *Motherwell* and Hamilton, general engineering is carried on.

The life of the coal-field is centralized in *Glasgow* (1,000,000). A number of routes converging on the city early made it important, but it was not until the Clyde was embanked and deepened that it became an important port. Among its industries are general engineering, the manufacture of cotton goods (compare the climate with that of Lancashire) and chemicals, and sugar refining. Important *shipbuilding* ports are Clydebank, Port Glasgow, and Greenock, the last named also refining sugar. Dumbarton uses the pure waters of Loch Lomond for bleaching; while *Paisley* is noted for cotton thread. Kilmarnock, on the Ayrshire coal-field, has engineering works, and Ayr and other ports on the Firth of Clyde export coal to Belfast. Finnart, Loch Long, is a terminal for oil-tankers.

Edinburgh (488,000) is the only large town by the small Midlothian coal-field. The capital of Scotland grew up around the castle-crowned rock standing in the gap between the Pentlands and the sea. Its industries include brewing, printing, and publishing (compare Oxford). Edinburgh was partly responsible for the growth of the paper-making industry in the valley of the Midlothian Esk, where the mills now use wood pulp imported from Sweden. Leith, the port of Edinburgh, imports dairy produce, wood pulp, and timber, while its exports include coal and pickled herrings which are in great

demand in the Baltic lands. Routes to the north run along the side of the Firth of Forth to *Stirling*, placed in the gap between the Ochils and the Campsie Fells. The modern railway crosses the Forth above Edinburgh and passes through Dunfermline, on the edge of the *Fife coal-field*, where Methil and Burntisland are coal-exporting ports and Kirkcaldy manufactures linoleum, using imported jute, linseed oil, and cork. *Perth*, in the gap between the Sidlaws and the Ochils, rose up at the lowest spot where the Tay was bridged. Here the route from the south-west divides: one branch crosses the Vale of Strathmore—a farming region—the other traversing the fruit-growing district of the Carse of Gowrie to Dundee. Once mainly a fishing port, *Dundee* (178,000) is now an engineering and manufacturing centre, making linen, sacks, bags, and sail-cloth with jute from Pakistan; marmalade and jam. From Dundee the railway to Aberdeen runs through Arbroath, Montrose, and Stonehaven.

The Highlands and their Margins. As seen from the Midland Valley, the great boundary fault running from Helensburgh to Stonehaven resembles a mountain range. North-west of it are the Highlands, the most extensive upland area in Britain. They are built up of old hard, crystalline rocks, mainly granites, schists, and gneisses that have weathered to form a poor infertile soil. The Highlands are the remnants of an ancient plateau, trenched by deep valleys that divide it into rounded masses of fairly uniform height. The general south-west to north-east direction of the valleys is well seen in Glenmore, a narrow rift, whose lochs are linked to form the Caledonian Canal, only large enough for the passage of small steamers. Glenmore divides the North-West Highlands from the Grampians, which culminate in Ben Nevis, 4,400 feet, the loftiest peak in the British Isles. On the west the Highlands extend to a rugged island-fringed coast indented by sea-lochs that resemble the fiords of Norway. From the water-parting, close to the west coast, short streams descend to the sea-lochs, and longer ones run eastward to the North Sea. Among the latter are the Tay and the Spey, whose valleys are used by the railway from Perth to Inverness. From Glasgow another line (branch to Oban) goes north to Fort William, at the south-west end of Glenmore. It continues to Mallaig, which, like the Kyle of Lochalsh, the terminus of a line farther north, is a port for the Hebrides.

Lying in the path of the on-shore westerlies, the Highlands have a heavy rainfall, especially in the west. The damp climate, cool summers, long winters, and rugged relief restrict settlement and limit crops to hardy ones, such as oats and potatoes. Large areas are devoted to sheep walks; and to deer 'forests' and grouse moors, which, like the salmon streams, are often let by their owners to rich sportsmen. But more useful from the point of view of employment is forestry: in recent decades existing forests have been enlarged by planting undertaken by the Forestry Commission.

Remarkable progress has been made in the development of water-power. Twenty years ago there were only a few *hydro-electric power* stations in the Highlands. Among them were those supplying aluminium factories at Kinlochleven and Foyers. Today there are about forty hydro-electric plants in this part of Scotland. They provide light and power not only for Highland towns and crofting communities, but also for towns on the East Coast Plain and some in the Midland Valley. The coming of electricity has greatly benefited the Highland peoples, whose future prosperity is tied up with the development of home industries, large-scale afforestation, the building of roads, and the expansion of the tourist trade.

In the Highland region must be included the Western Isles, whose wild and rugged slopes rise high above storm-tossed seas. The islands may be divided into the Inner and Outer Hebrides, separated by the Minch, a submerged rift valley. Chief among the Inner Hebrides are Mull and Skye, built mainly of igneous rocks which form the Cuillin Hills in Skye, and rise in terraces on both sides of the Sound of Mull. Portree is the chief town in Skye.

The principal island in the Outer Hebrides is *Lewis and Harris*, from whose port of Stornoway steamers run to the Kyle of Lochalsh. The island-crofters grow oats and other crops for their own use, breed a few cattle, and rear sheep whose wool is made into homespun cloth, like 'Harris tweeds'. There is some fishing, but an attempt some years ago to establish a modern fishing industry was a failure.

The Orkneys and Shetlands are more closely linked with North-East Scotland. The *Orkneys* are separated from the mainland by Pentland Firth, through which tidal currents race at great speed, making navigation difficult. Forming a detached portion of the Old Red Sandstone Plain of Caithness, the islands are relatively low.

Cattle are grazed and poultry are reared. There are air services from Kirkwall, on the island of Mainland, to Aberdeen.

The rugged *Shetland group*, some 50 miles north of the Orkneys, resembles the Highlands in structure and scenery. Sheep grazed on the moorlands yield fine wool. Lerwick, the chief town, a small fishing port, is linked by air with Aberdeen.

FIG. 116. Scotland: The Highlands.

Nine-tenths of the inhabitants of Northern Scotland live on the *North-East Coastal Plain* which margins the Highlands on the east. Lying in the rain shadow of the mountains, the plain has a relatively low rainfall. The sandstone weathers to a rich soil on which oats, barley, and root crops are grown and on whose pastures shaggy, horned cattle are reared. *Aberdeen* (187,000), situated at the point where the *Dec* and *Don* valleys reach the coast, is a university town, and one of the chief fishing ports in the British Isles. Other fishing centres are *Peterhead* and *Fraserburgh*, somewhat to the north, and *Wick*, in *Caithness*. *Inverness*, lying at the northern end of *Glenmore*, is the chief centre of the *Moray lowlands*, composed like the *Plain of Caithness* of *Old Red Sandstone*.

The Isle of Man. In the Irish Sea, almost midway between England, Scotland, Wales, and Ireland lies Man (230 square miles), a mountainous island (Snæfell, 2,030 feet) which in structure and relief closely resembles the Wicklow Mountains and the Welsh

FIG. 117. The Isle of Man.

Uplands. The Curragh, in the north, is the only considerable lowland area. Owing to its maritime situation the climate is mild. Oats, barley, potatoes, and turnips are the chief crops; sheep are pastured on the moorlands and cattle are reared; there is a little lead mining and some fishing is carried on round the coasts. But the chief occupation is catering for visitors, especially those from the industrial north, who in summer flock to this island with its picturesque glens, pleasant beaches, and heather-clad moors.

Douglas, the capital and chief sea-side resort, is linked by rail with Ramsey in the north-east, Castletown in the south, and the quaint old port of Peel in the west. From Douglas steamers run to Liverpool and Heysham, while air services link it with Liverpool, Carlisle, and Dublin. Man is administered in accordance with its own laws by the Court of Tynwald.

EXERCISES

1. Name and account for the position of the chief shipbuilding areas in the British Isles. Describe *one* of them in detail.
2. Give an account of *one* of the following routes, paying attention to the type of scenery and industry: railway from London to Fishguard; the Great North Road from London to Darlington.
3. (a) Why has South-West England so favourable a climate? (b) What branch of agriculture depends mainly on the climate? What other industry depends on the climate and scenery?
4. (a) Give an account of the relief, climate, and occupations of the English Lake District. (b) Name four British lakes used as reservoirs, mentioning in the case of each the towns they supply.

5. State briefly some of the main factors that have contributed to the importance of Shrewsbury, Sheffield, Birmingham, Edinburgh, Carlisle, and Oxford. Illustrate your answers by sketch-maps.

6. How do you account for the location of the cotton industry in Lancashire? From what countries does this county obtain its raw cotton? Name (i) the chief port, (ii) the chief cotton market town, (iii) *three* spinning and *three* weaving towns, and *three* engaged in bleaching and dyeing, accounting for the location of *one* in each group.

7. (a) Describe briefly the geographical factors influencing the position of large commercial ports. (b) Name *two* such ports in England, *one* in Wales, and *one* in Scotland. Describe the position of each and outline its hinterland. In the case of each port name *two* of its chief exports and *two* imports, together with *one* source from which each is obtained.

8. Describe carefully the relief and drainage of the Pennine Chain, indicating any important gaps in that upland.

9. Three men, A in the lowlands of South-West Scotland, B in Norfolk, and C in Kent, each make their living by farming the land, but their work is not necessarily the same. Suggest, giving your reasons, the differences in the types of farming.

10. Name *two* coastal districts in England and *one* in each in Wales and Scotland which are popular holiday resorts. Give a description of *one* only of those you name, and state to what geographical conditions you ascribe its popularity.

11. From the six towns Aberdeen, Blyth, Bradford, Goole, Grimsby, and Swansea select *three* so as to include *one* manufacturing town, *one* coal-exporting port and *one* fishing port. Show for each town how geographical factors have favoured the development of its particular occupation. Illustrate your answer with sketch maps.

12. Name *two* important centres of the heavy chemical industry in England. In the case of *one* of them show how geographical factors have favoured its development in the area. Give a sketch map.

13. (a) Name the five chief towns in the Potteries. (b) Whence do the Potteries obtain the following raw materials for their main industry: coal, china clay, and flints? How are the last two materials conveyed to the Potteries? Name one other place in the British Isles engaged in making pottery.

14. Show by sketch-maps the traffic routes by which manufactures of the Black Country reach the following ports: Liverpool, Hull, London, Bristol.

15. What are the chief occupations of the people living (i) along the Eastern Plain of Scotland, and (ii) in the Highlands? How do you account for the sparse population of the latter region?

16. Name the chief woollen manufacturing areas in Great Britain, *outside* Yorkshire, and account for their location. From what countries do we import most of our raw wool? Name *two* of the chief ports of entry.

17. What do you mean by the London Basin? Give a short account of the basin with special reference to the position of London.

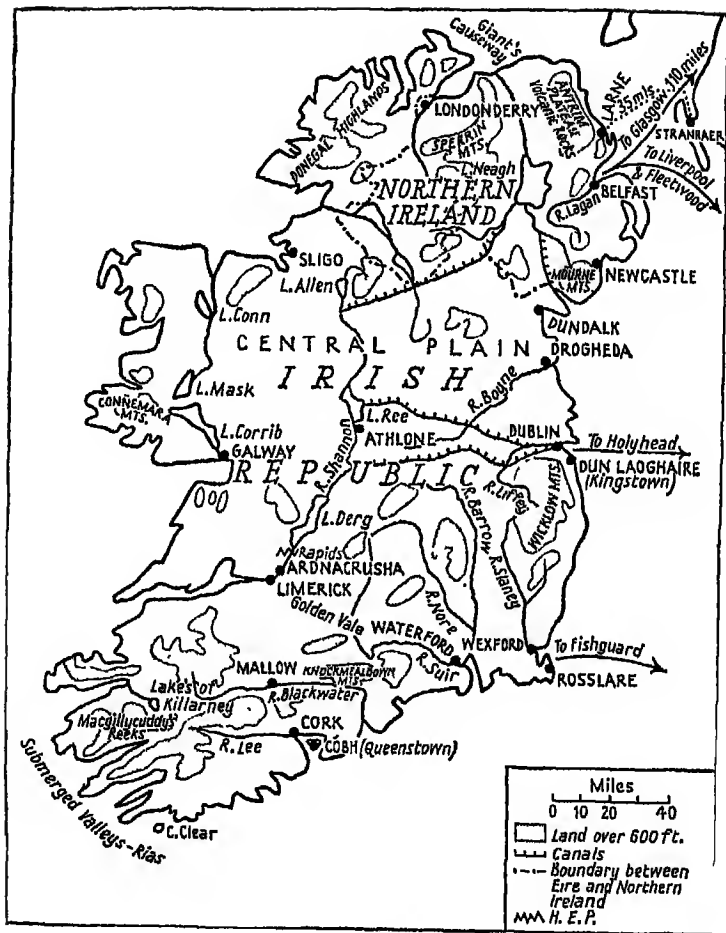

FIG. 118. Ireland.

II. RURAL SCENES IN SCOTLAND AND WALES

(Above) Loch Linnhe. Alluvial strips beside the loch are successfully cultivated by crofters. The surrounding heather-clad hills provide pasture for sheep, as do the Welsh Uplands (below) where shepherds, aided by their sagacious dogs, are driving a flock of sheep down the valley to the farm. On the moorlands dry stone walls enclose large tracks of pasture over which the sheep wander (see p. 155).

12. CONTRASTING INDUSTRIES

(Above) The uncompleted hulls in the foreground will be floated down the slipways into the Clyde, along whose banks lie some of the chief shipyards in the world. The gantries are a typical feature of such shipyards. (Below) On this Bleach Lawn, in Northern Ireland,

IRELAND

Ireland consists of a much-denuded Central Plain surrounded by groups of relatively low mountains many of which display striking structural resemblances to the ancient highland areas of Britain. In Connaught the Connemara Mountains are separated from those of Mayo by Clew Bay. To the north-east the Donegal Highlands rise from the sea to a height of 1,900 feet. Between the Donegal Highlands and the Sperrin Mountains the Foylc flows northward into the lough that bears its name. To the east of the Sperrin Mountains lies the valley of the Bann, draining Lough Neagh, the largest lake in the British Isles. North-east of the lowlands drained by the Bann and the Lagan is the Antrim Plateau, whose steep cliffs, composed of chalk covered with basaltic rocks, rise high above the waters of the North Channel separating Ireland from Scotland. The volcanic rocks of the Antrim Plateau were formed at the same period as those of Western Scotland. In the Giants' Causeway the basaltic lava has cooled into regular hexagonal columns.

North-west of the granitic Mourne Mountains, which resemble in their structure and direction the Southern Uplands of Scotland, lies the valley drained by the Blackwater to Lough Neagh. In this valley, a continuation of the Rift Valley of Midland Scotland, lies the small Tyrone coal-field. South of the Liffey the Wicklow Mountains rise in Lugnaquilla to over 3,000 feet. In geological age, structure, and landscape these beautiful uplands resemble the Welsh Highlands on the opposite side of the Irish Sea, and like the latter they have been glaciated and contain numbers of U-shaped valleys and cirques.

In Southern Ireland a well-marked series of upfolds (anticlines) and downfolds (synclines) form parallel ridges and valleys running from west to east. To the north of the upfold forming the Knockmaldown Mountains the Suir runs east in the corresponding downfold to Waterford Harbour, into which the united waters of the Nore and the Barrow also flow from the north. The Bandon, Lee, and Blackwater flow east in similar valleys, but in their lower courses they turn south, flowing through transverse gorges into rias which form respectively the harbours of Kinsale, Cork, and Youghal. In the south-west other rias form Dingle Bay, Kenmare Bay, and Bantry Bay. Unlike the sea-lochs (fjords) of Scotland, the banks of the rias

are gently sloping, becoming narrower and shallower towards their heads. The coast is fringed by numerous islands, including Valencia Island, whence cables run across the Atlantic, and Cape Clear Island, with its lighthouse. Between Dingle Bay and Kenmare Bay rise the Maegillycuddy's Reeks, the highest mountains in Ireland, at whose foot nestle the picturesque island-studded Lakes of Killarney.

The *Central Plain* covers one-third of Ireland, and though ringed by uplands it extends to the sea in many directions. On the east is the broad entry of Meath. On the west the lowlands reach the Atlantic round the Shannon estuary, at the heads of Galway, Clew, Killala, and Sligo Bays, and along the valley of the Erne. On the north-east other routes lead seawards along the lowlands drained by the Foyle, Bann, and Lagan.

The plain is floored with limestone covered for the most part with boulder clay deposited by the Ice Sheet. The copious rains leave much surface-water, some of which collects in clay hollows, forming swamps and shallow lakes, where peat moss and other damp-loving plants thrive. This process has been going on for thousands of years: as plants have died they have been replaced by others, and gradually the mass of vegetation and mud has formed a *bog*. The decayed vegetation which in the course of ages has accumulated in the bogs forms peat, which may be regarded as a half-way stage to coal. With the exception of the Bog of Allen, most of the Irish bogs have been drained, thus allowing the peat to be cut for fuel. The plain is dotted with small *morainic dammed lakes*, while in places the streams have expanded into *solution lakes*, formed by the dissolution of the soluble limestone. Among them are loughs Conn, Mask, and Corrib, and those through which the Shannon flows.

The Shannon (250 miles), the longest river in the British Isles, rises in the North-West Highlands, and flows through Loughs Allen, Ree, and Derg, past Limerick into a broad estuary. From the point where it leaves Lough Allen to the southern end of Lough Derg, the Shannon falls only 60 feet in some 80 miles, or 9 inches per mile. But between the latter lough and Limerick the river cuts its way through a gorge, falling over 100 feet in 20 miles. The building of a canal has enabled the fall of water to be utilized by the Ardnacrusha power-station, which supplies much of the Irish Republic with electricity.

Though Ireland is geographically a unit, yet, on account of historical considerations, it was divided in 1922 into two states: Eire, ranking as a Dominion, and Northern Ireland. In 1949 Eire severed her ties with the Commonwealth and became a Republic. Northern Ireland is an integral part of the United Kingdom.

The Irish Republic, comprising about five-sixths of Ireland, has a population of nearly 3 millions. It is primarily an agricultural country, for it has few minerals and only one small coal-field, in Kilkenny. But thanks to the abundant electricity supplied by the Shannon Power Station, and to government aid, there have been established a number of light industries manufacturing consumer-goods (i.e. those for personal and domestic use), ranging from razor-blades to stockings and saucepans. These industries, widely dispersed so as to spread employment over the country, occupy about one-third of the working population. Nevertheless, nearly half the people depend for their livelihood on agriculture, the majority being small peasant farmers.

The damp climate is better suitable to grass than to cereals and out of every 100 acres of cultivated land only fourteen are arable. Oats and potatoes are widely grown, and barley is cultivated in the dry, sunny, warm south-east. The pastures of the Central Plain are devoted mainly to dairying and the rearing of horses and pigs. As the call for liquid milk is limited much is made into butter, an important export. Beef-cattle are sent from the west of the Plain eastward to be fattened on the richer pastures of Meath, and many are shipped to Birkenhead, and brought to prime condition on the English plain. The west of Ireland, and Donegal in particular, is a very thinly peopled region, for the soil is poor, the rainfall very heavy, and only with difficulty do the inhabitants wrest a living from the land and the sea that washes their coasts.

Dublin (500,000), the capital, on a fine harbour in the centre of the east coast, is the natural outlet for the Central Plain. Its exports include cattle, horses, and beer, and its industries the manufacture of tobacco, biscuits, and soap. Among its chief imports are wheat, coal, and iron and steel goods. Kingstown (Dun Laoghaire), on Dublin Bay, is a packet station for Holyhead, *Cork*, standing at the point where the Lee enters Cork harbour, manufactures agricultural machinery, is a brewing and distilling centre, and exports dairy

produce. Queenstown (Cobh), on an island in the harbour, is a port of call for trans-Atlantic liners. In the south-east, Waterford and Wexford are small ports and market towns, and Rosslare the packet station for Fishguard. The centre of an agricultural region, *Limerick*, at the head of the Shannon estuary, cures bacon, makes lard and condensed milk, and imports coal and grain for use in Western Ireland. On the right bank of the Shannon estuary is *Shannon Airport*.

Northern Ireland. Though Northern Ireland comprises only one-sixth of the country, it contains nearly 30 per cent. of the population. Agriculture is important, oats, potatoes, flax, and hay being among the principal crops. The damp climate is well suited for flax, while ample supplies of pure water are available for retting it, and for use in the various stages of the *linen*-manufacturing industry for which Northern Ireland is justly famed.

Belfast (438,000), the capital, stands where the Lagan enters Belfast Lough, whence sea-routes go to Glasgow, Barrow, Heysham, Fleetwood, and Liverpool. There is little coal or iron ore in Northern Ireland, but coal is imported from the Scottish and Cumberland coal-fields and steel from Furness. So, thanks to cheap water-transport, and the initiative of her people, Belfast has become one of the leading shipbuilding areas in the British Isles. Heavy (including agricultural) machinery, linen, matches, rope, and tobacco are manufactured in the city, which is also engaged in brewing, distilling, and flour-milling. To the north-east is Larne, a packet station for Stranraer (36 miles), in Scotland. *Londonderry*, on the Foyle, makes linen goods and shirts. To the west lies part of the Irish Republic, separated by tariff barriers from Northern Ireland: thus deprived of a portion of her natural hinterland, the trade of Londonderry has suffered since the partition of the country.

EXERCISES

1. Describe (a) the physical features, and (b) the climate of Ireland. Show how both combine to affect the human activities.
2. (a) Why do the relief and climate of the Central Plain of Ireland make it well suited for dairy farming? (b) Describe briefly the dairy and other farming activities of this area. (c) Name (i) four exports, and (ii) two imports

dependent on farming. (d) Name the two chief ports in the Irish Republic exporting farm produce. (e) In what ways has the Shannon Power Scheme assisted the development of small scale manufactures in the Irish Republic? (f) What manufactures are best suited to the geographical conditions of the Irish Republic? Give your reasons. (g) Are such manufactures likely to be concentrated in a few areas, or scattered throughout the country? Why?

3. Among the industries of Belfast are shipbuilding, linen manufacturing, and the making of agricultural machinery. How do you account for the location of these industries in Belfast?

4. Select *one* thickly peopled, and *one* thinly peopled area in Ireland. Explain how, in each case, the density or sparsity is affected by the relief, climate, and resulting occupations.

5. (a) State in what respects Ireland and Wales differ so markedly in (i) relief, (ii) power resources. (b) What are the differences in *pastoral* farming in these two countries, and to what geographical factors are the differences due?

CHAPTER XIII

COUNTRIES OF WESTERN EUROPE

(excluding the British Isles)

FRANCE

FRANCE, the second largest country in Europe, has an area of 213,000 square miles and a population of 43½ millions. Washed by the

FIG. 119. France: Natural Regions.

English Channel on the north-west, by the Atlantic on the west, and the Mediterranean on the south-east, France is well placed for over-seas trade. Her maritime situation also favourably affects her climate, which in the north-west is insular, in the south-east Mediterranean, and only in the east approaches continental conditions.

Of her land frontiers the most vulnerable is the north-east forming the boundary with Belgium and Germany. Running from the Northern Plain, and then across the Ardennes and other uplands to the Rhine, it was overrun by German armies in 1870-1 and in both World Wars. Elsewhere the Pyrenees separate France from Spain, the Alps from Italy, and the Alps and the Jura from Switzerland.

FIG. 120. France; Inland Waterways.

FIG. 121.

The French river and canal system, which is linked with those of Belgium and Germany, is important in the transport of the country (Fig. 120). Rivers, like the Seine and its tributaries, the Saône and the Rhine, all navigable for considerable distances, are linked by canals. They are much used for carrying heavy, bulky, and relatively non-perishable commodities, like coal, ore, grain, and building materials.

More than half of France consists of lowlands of great fertility. Forests cover over 20 per cent. of the country, and only 10 per cent. consists of unproductive moor and mountain land (see Fig. 123).

Of the total area, 66 per cent. is cultivated, of which amount 60 per cent. is arable and the rest pastoral land. In France, out of every 100 workers, 35 are engaged in agriculture, compared with 6 in the United Kingdom. There are few large estates. Most of the farms are small and the majority are worked by their owners. In recent years there has been a drift from the rural areas to the towns, but, in spite of this, agriculture is the mainstay of the Republic and the landowning peasantry are the backbone of the country.

France may be divided into a number of *Natural Regions* differing

FIG. 122. Relief Model of the Paris Basin.

somewhat in configuration, climate, and products, but linked with each other to form a united whole. The chief of these regions (Fig. 119) are (1) the Paris Basin, (2) Brittany, (3) the South-West, (4) (a) the Rhone-Saône Valley and (b) Mediterranean France, (5) the Central Plateau, (6) the Alps-Jura Region, (7) the Pyrenees, and (8) Eastern France.

(1) The Paris Basin and Northern France. The Paris basin may be compared to a nest of saucers with the smallest in the centre, but it should be noted that in the north-west the concentric circles are broken by the English Channel (see Fig. 122). The land slopes gradually upwards from the centre, falling, on the side away from Paris, by steep chalk or limestone escarpments to narrow clay plains.

Rivers, such as the Seine and its tributaries the Oise and the Marne, have cut gaps through the encircling escarpments, and in these gaps stand towns, and through them run roads and railways.

The variety of soils in the basin is reflected in the vegetation and crops. Much wheat is grown in *Beauce*, a limestone plain south-west of Paris, and in *Picardy*, where many acres of loam-covered chalk are also planted with sugar-beet. East of Paris the land rises to an escarpment overlooking *Dry Champagne* (chalk), a sheep-grazing area, with vineyards on sun-facing slopes, which yield grapes for making champagne. Reims, the chief centre of the wine trade, has long been a woollen manufacturing town. Also known for its vineyards is the valley of the Loire, where *Orleans* stands at the most northerly point on the river.

In its climate and products *Normandy* resembles Devon and Somerset, and, like these English counties, it is famed for its dairy-cattle and cider-apples. *Rouen*, at the head of ocean navigation on the Seine, is the chief cotton-manufacturing town in France. It imports raw cotton through *Havre*, the second port in France, which, like Dieppe, Boulogne, Calais, and Dunkirk, is a packet station for cross-Channel steamers.

To the north of the Paris Basin lies the French portion of the *Franco-Belgian coal-field*, where the closely linked towns of *Lille*, *Roubaix*, and *Tourcoing* manufacture cotton, linen, and woollen goods. Other textile towns are *Valenciennes* and *Cambrai*. Local supplies of wool and flax gave rise to textile manufactures, but now much raw material is imported. Flax comes from Belgium. Raw cotton, wool, and jute (for sacks) enter through Dunkirk.

Mainly owing to her commanding position, *Paris* (2,725,000) grew from a fishing settlement, on an island in the Seine, to be the capital of France. It is the chief inland port in France. Routes by road, river and canal, rail, and air converge on Paris from all directions (see Figs. 120, 122, and 124). Like London, the city is a great industrial centre. It is noted for its artistic products, is a leader of fashion, manufactures motor-cars, boots and shoes, refines sugar, grinds flour, and is a great wool market. It makes paper, and like most university towns is a publishing centre.

(2) **Brittany.** The interior of Brittany consists mainly of uplands, whose old rocks have weathered to form infertile soils covered in

part with forests and heaths, and in part devoted to the cultivation of crops like rye and oats which can be grown in a damp climate and on poor soils. In the coastal valleys and around the bays, especially those facing south, early fruit and vegetables are produced for the Paris market (compare Devon).

Many of the Bretons, like their neighbours across the Channel, are sailors and fishermen. Among the largest fishing ports are

FIG. 123. France: Crops.

St. Malo and Lorient. Brest and Cherbourg are naval stations, and the latter is also a port of call for trans-Atlantic liners. *Nantes*, at the head of the Loire estuary, one of the two capitals of Brittany (the other being *Rennes*), has shipyards and chemical, cotton, and tin-plate factories. Its outport is *St. Nazaire*.

The Channel Islands (*Jersey*, *Guernsey*, *Alderney*, *Sark*), lying off the coast of Brittany, are the only remaining part of

Britain's heritage from the Normans. Their mild climate favours the production of early fruit, and vegetables, the bulk of which are marketed in England, and also makes them a favourite holiday resort.

(3) **South-West France**, or the Basin of Aquitaine, is watered by the Dordogne and the Garonne, which carry nearly all the drainage of the area to the Gironde estuary. There is sufficient rain and the summers are warm enough to allow maize to be grown. It is found mainly in the west, while farther inland much wheat is cultivated on the clay plain round *Toulouse*. The district round *Bordeaux* is noted for its vineyards, which produce excellent wine, while north of the Gironde estuary brandy is distilled from grapes grown in the basin of the Charente. South of the Gironde estuary the sandy district, called the *Landes*, once a waste covered with rough pasture, has been drained and planted with pines which yield resin, turpentine, tar, timber and pit-props. *Bordeaux* (260,000), on the edge of

firm ground at the head of the Gironde estuary, has large iron and steel industries, refines sugar, and exports wine. Through *Toulouse* (220,000), a market town and route centre, pass the road, railway, and canal which run, by way of the Gate of Carcassonne, to the lower Rhone valley and the Mediterranean.

(4) The Rhone-Saône Valley and Mediterranean France.

From early times the Rhone-Saône Valley, running between the Alps and Jura on the east and the Central Plateau on the west, has formed a corridor leading from the Mediterranean to the Paris Basin (across the Côte-d'Or), as well as an important route linking the former region with the Rhine Valley.

Climatically we may divide the Rhone-Saône Valley into two portions. North of Valence (just below the confluence of the Rhone and Isère) the climate resembles that of Central Europe: the summers are hot, the winters cool, and there is rain at all seasons, but most in summer. South of Valence the climate is of the Mediterranean type with hot, dry summers and warm, moist winters. The vine is grown throughout the valley. On the slopes of the Côte d'Or are produced the famous wines of Burgundy, where Dijon, the chief centre of the trade, is a nodal point and important railway junction. The olive, which cannot stand cold winters, is confined to the lower portion of the valley where, too, are grown early vegetables and fruits, as well as mulberry trees whose leaves are used to feed silkworms. In winter sheep are grazed on the plains of the Rhone delta, but in spring they are taken by train to the upland pastures of the French Alps, which remain fresh when those of the lowlands are withered—an interesting example of *transhumance*.

The valley lacks minerals, but some coal is found on the margin of the Central Plateau (St. Étienne), while the Alpine streams furnish hydro-electric power. *Lyons* (470,000), the third largest city in France, stands at the junction of the Rhone and the Saône. The chief silk-manufacturing town in the world, it supplements local supplies with raw silk from Italy, China, and Japan. Most of the overseas trade of the valley passes through *Marseilles* (660,000), the premier French port, lying east of the Rhone delta. Among its imports are palm oil and kernels, used with local olive oil in its soap factories; wheat and wool; petroleum for refining; and coal and salt for its chemical industries.

East of Marseilles the railway runs along the coast, by way of the naval base of Toulon, to the *Riviera*, whose equable climate and scenery attract many visitors to Cannes, *Nice* (240,000), Monte Carlo, and smaller centres. The high mountain barrier protects this coastal district from the cold northerly winds, while the southward-facing slopes get the full benefit of the sun's rays.

Corsica forms part of Mediterranean France. Geologically a crust-block, it is a mountainous island surrounded by narrow coastal plains. Part is forested, and much is covered with scrub (*maquis*) consisting of evergreen shrubs. Farming, fishing and sheep rearing are the chief occupations. Ajaccio is the port-capital.

(5) **The Central Plateau** rises towards the south-east, where its edge is formed by the Cevennes which sink steeply to the Rhone valley. The old rocks weather to form poor soils, best suited to rye and oats, but in the upper Allier valley, filled with rich volcanic deposits, wheat, sugar-beet, and vines are grown. Associated with former volcanic activity are the extinct volcanic cones of the Auvergne, and hot springs, such as those at Vichy, in the Allier valley. In the limestone Causses, in the south-east, the Tarn and other rivers have cut deep gorges. Sheep are grazed in this area; and many cattle are pastured on the Millevaches plateau in the rainy north-west. The Central Plateau is sparsely peopled, and settlement is confined to the valleys. In that of the upper Allier, *Clermont Ferrand* stands near the base of the extinct Puy de Dôme. *Limoges*, in the Limousin, is noted for its cattle fairs, tanneries, and potteries (local kaolin). On the eastern margin of the plateau there are small coal basins at *St. Étienne*, a steel and silk-manufacturing centre, and *Le Creusot*, which makes munitions.

(6) **The Alps-Jura Region.** From the Alps and the Jura numbers of streams descend to the Rhone and Saône, whose valleys, as well as those of the Doubs, Isère, and Durance are, in part, followed by railways. In recent years many streams have been harnessed for electricity, which supplies power for aluminium factories in the Durance and Isère valleys, and also for railways. In late spring sheep are brought by rail from the lowlands to feed on the upland pastures: their skins, together with local and imported goat-skins, are made into gloves at Grenoble, on the Isère, which also manu-

factures paper. Chambéry, on the Mont Cenis route to Italy, manufactures silk; Besançon, on the Doubs, makes watches.

(7) **The Pyrenees** have an average elevation of from 6,500 to 10,000 feet. On the Spanish side they sink gradually by a series of plateaux to the Meseta: on the French side they fall steeply, being trenched by wooded valleys, down which the rivers (many harnessed for hydro-electric power) flow in series of gorges and basins. The Pyrenees contain some small glaciers. Passes across the mountains are high and relatively few. The main railway lines from France to Spain run from Bayonne round the western end, and from Perpignan round the eastern end of the mountains, but a line from Pau to Saragossa, and another from Toulouse to Barcelona, cross the chain. The latter runs to the west of the little mountain state of *Andorra*.

(8) **Eastern France** may be divided into *Alsace* and *Lorraine*.

The plateau of *Lorraine*, rising to the east of the Marne valley, and forming a link between the Vosges and the Ardennes, is crossed by the Meuse and the Moselle. In parts thickly forested, and a region of poor soils, its wealth lies in its iron ore. Blast furnaces, such as those at *Nancy* (114,000), are fed with coking coal from the Ruhr and the *Saar Basin*.¹ Strategically the importance of this region is seen in the Maginot Line, designed to defend the eastern frontier of France, but turned by the Germans in the last war. Included in it were Metz on the Moselle, Verdun on the Meuse, and Toul, commanding the gap leading from the valley of the Meuse to that of the Moselle. Outside the few large towns and mining areas, most people earn their living by farming and forestry.

Alsace, stretching from the forested slopes of the Vosges to the Rhine, reverted to France, with Lorraine, in 1919. Forming the western portion of the Rhine rift valley, its climate and crops resemble those on the German side of the river. Vineyards clothe the lower slopes of the Vosges; fields of wheat, barley, and tobacco, hop-gardens and orchards spread over the plain. The deposits of potash are even richer than those at Stassfurt in Germany. *Strasbourg* (180,000), on the Ill, near its confluence with the Rhine, the chief city and an important river port, commands routes through the Rhine valley, and also by the Lorraine Gate to Nancy. Colmar

¹ Incorporated in Germany 1 Jan. 1957.

manufactures cotton goods and rayon, while Mulhouse is also engaged in the cotton industry.

Transport and Trade. The rail, road, and canal system of France is best visualized by noting how the routes converge on

FIG. 124. France: Transport and Coal-fields

Paris. The main railways avoid the uplands, but communications between the three principal lowland areas are relatively easy. The Paris Basin is linked by the Gate of Poitou with the South-West, and across the Côte d'Or with the Rhone-Saône valley. The latter route is followed by the Paris-Lyons-Mediterranean Railway. Routes from the lower Rhone valley and the Mediterranean to the South-West run through the Gate of Carcassonne, between the Pyrenees and the Central Uplands.

About three-fifths of the French coal is obtained from the

Franco-Belgian coal-field. But as home supplies are inadequate, coal and coke are leading imports. From the Lacq oil-field, in the foothills of the Pyrenees, natural gas is piped to Paris and other industrial centres. With rich iron-ore resources, France ranks high among iron- and steel-producing countries. Half her electricity comes from hydro-electric power-stations, the chief being in the Alps, Jura, Vosges, and Pyrenees. These supplies have aided the development of electro-chemical industries, whose products, with heavy chemicals, such as sulphur, a by-product of natural gas (Lacq field) help to place chemicals at the head of French exports.

FIG. 125.

The effect on French foreign trade of the European *Common Market* remains to be seen. The Common Market, which came into being on 1 January 1959, is an association of States whose aim is to abolish all trade restrictions between themselves, and to set up a common tariff wall against all other countries. Besides France, the members of the Common Market are Belgium, the Netherlands, Luxembourg, Western Germany, and Italy (see p. 203).

EXERCISES

1. Describe the structure and relief of the Paris Basin, and show how they affect the human activities of the region. Give a sketch-map.
2. Draw a sketch-map of France and indicate upon it the principal natural regions. Select *one* of the more important regions (excluding the Paris Basin) and show how its relief, climate, and soils are related to its characteristic products. Name the chief port, or ports, through which the surplus products are exported.
3. Show how the relief of France has affected (a) railway communications, and (b) the canal system. Describe the route by which goods are conveyed by inland waterways from the Franco-Belgium coal-field to Paris.
4. (a) Name the chief centres in France for the manufacture of the following textile goods: cotton, woollen, silk, rayon, and linen. Tabulate your answer. (b) In the case of *one* of the above manufactures, choose

one important centre of production and account for the location of the industry in that area. Name also the port, or ports, through which this centre obtains its raw material, and state the main sources of supply.

5. How do you account for the fact that in France vines are not grown on an economic scale north of the Loire and Aisne valleys? Name the chief wine-producing areas in the country and the principal towns, connected with the industry, in each area.

6. Illustrating your answer by sketch-maps, describe the positions of Bordeaux, Marseilles, and Havre, pointing out the geographical importance of each port. Compare their trade.

BELGIUM AND HOLLAND

BELGIUM

Belgium is little more than one and half times the size of Wales, yet this kingdom, with a population of 9 millions, or 775 persons to the square mile, is one of the most densely peopled countries in Europe. Belgium is a buffer state lying between more powerful neighbours—France and Germany—and her position, athwart the European Plain, has too often made her a battle-ground of Europe.

Across the Northern Plain the Schelde flows in a north-easterly direction to Antwerp, below which it enters the North Sea by a delta. In the south the Meuse has cut a deep valley through the Ardennes, but after receiving at Namur the Sambre from the south-west, the united stream follows the direction of this tributary along the foot of the mountains to Liège, where it turns north and flows across Holland (as the Maas) to the sea. From early times the Sambre-Meuse valley has formed an important route leading, by way of the Oise valley, from the Paris Basin to the Rhine at Cologne.

Belgium may be divided into three Natural Regions: (1) the Northern Plain; (2) the High Plains; and (3) the Ardennes.

(1) **The Northern Plain**, extending westward into France and eastward into Holland, stretches from the High Plains to the low, sandy coast bordered by sand dunes and devoid of good natural harbours; for those of the packet stations of Ostend and Zeebrugge are artificial and constant dredging is necessary to keep them free from silt. Of recent geological formation, the plain is composed mainly of sands and clays with the addition of peaty soils in the coastal region. Cattle are reared, and on the intensely cultivated

13 RECLAIMED LAND—A GREAT EUROPEAN CAPITAL

(Above) Reclaimed land in Holland. A general view of farm lands in the North-East Polder fronting Lake IJssel (see Fig. 129). (Below) Paris. From a fishing settlement on these islands in the Seine, Paris grew until it is now a city with over 3 million inhabitants. On the Ile de la Cité, Notre Dame may be seen facing the square. The Latin Quarter lies on the left bank of river (right).

14. THE LAUTERBRUNNEN VALLEY, BERNESE OBERLAND

The flat floor of the main U-shaped valley rises by steep cliffs to the *hanging valleys* above one of which may be seen on the left. These *hanging valleys* are covered with glacial debris which forms a rich soil, clad with pastures on which cattle feed. From these gently graded side-valleys streams descend by waterfalls which furnish power to generate electricity.

land wheat, sugar-beet, hops, tobacco, and flax are grown, especially in the west on the clay soils of Flanders. In the east rich loam soils are devoted mainly to fruit cultivation and market-gardening.

FIG. 126. Holland and Belgium: Natural Regions.

The waters of the Schelde, the Lys, and other streams are used for retting flax, which is made into linen at Tournai, on the Schelde; Courtrai, on the Lys; and Ghent, at the confluence of these two streams. Ghent, also noted for its cotton goods, was, like quaint old Bruges, a great woollen-manufacturing centre in the Middle Ages. In the north-east of the plain the sandy Campine district, which extends across the frontier into the Dutch province of Limburg,

consists mainly of moorland and marsh. It may one day become an important industrial region, for beneath the overlying sand lies coal,

FIG. 127. Holland and Belgium: Coal-fields and Principal Canals.

which, though lying at a considerable depth and expensive to work, is now being mined.

Antwerp (632,000), the premier port of Belgium, lies at the head of the Schelde estuary, the mouth of which is in Dutch territory. From Antwerp heavy and bulky goods are dispatched by canal to all parts of Belgium; and the city is noted for its sugar-refineries, distilleries, and diamond-cutting works. *Brussels* (1,000,000), stands on the Senne (a tributary of the Schelde), midway between Antwerp and the industrial district to the south. It is the focus of Belgium's rail,

road and canal system, and owing to its central position is well placed to be the capital.

(2) **The High Plains**, lying between the Northern Plain and the Ardennes, are floored mainly with Tertiary rocks. On them oats, wheat and barley are all cultivated, while dairy cattle are grazed on their pasture lands. But the chief wealth of this region lies in its rich seams of coal. The *Belgian Coal-field*, extending along the Sambre-Meuse valley, forms part of the coal basin stretching from Anzin, in Northern France, to Aachen, in Germany. From Mons

FIG. 128.

to Liège a line of mining and manufacturing towns is strung along the valley. *Mons* is noted for its breweries, distilleries, sugar-refineries, and glass works; *Charleroi* for its plate-glass and hardware. Charleroi and Liège make hardware (ironmongery, etc.), an industry owing its origin to zinc mines at Verviers nearby. But as the mines are now almost exhausted, supplies are obtained from Australia, entering through Antwerp, and thence by the deep-water Albert Canal. The great iron and steel plants at *Liège* (405,000), which formerly drew much iron ore from the Belgian coal-fields, now depend on ores from Luxembourg and Lorraine.

(3) **The Ardennes** present a great contrast to the rest of Belgium. They are the most thinly peopled region for, apart from the fact that they are the only upland area in the country, their ancient (Primary) rocks have weathered to form rugged scenery and infertile soils. Moreover, their climate tends to be extreme. Much of this highland region is clad with moorland and forests of beech, oak, and pine. The peasants work hard tilling their fields of rye, oats, and potatoes; grazing sheep on the moorlands, feeding pigs on the acorns and beech-mast in the forests, and tending dairy cattle reared on the more fertile western slopes of the uplands.

Most of the inhabitants of Southern Belgium are Walloons, akin to the French and speaking a dialect very like that of their neighbours across the frontier. They differ greatly both in appearance and speech from the Flemings living in the north, who more closely resemble the Dutch and the Germans.

Luxembourg is a small Grand Duchy lying in the south-east of the forested Ardennes. Agriculture is important, but the chief wealth of this state lies in its iron ore: much is sent to Liège, and much is smelted locally over coke imported from Belgium. The chief iron and steel plants are in the south.

Belgium, the Netherlands, and Luxembourg are members of a Customs Union, known as *Benelux*; and of the *European Coal and Steel Community*. Both of these organizations will gradually become merged in the European *Common Market*.

HOLLAND OR THE NETHERLANDS

Holland, somewhat larger than Belgium, is the most densely peopled country in Europe. There are 845 persons to the square mile, and the population is nearly 11½ millions.

Nearly half of Holland has an elevation of only 3 feet above mean sea-level, while in the west an area, comprising a quarter of the country, is actually below sea-level. Only in the low plateau of South Limburg, bordering the Ardennes, is the land over 300 feet, and even here the highest portion scarcely exceeds 1,000 feet. Holland has been built up of sediment brought down by the Rhine, Maas (Meuse), and Schelde. As many of the rivers now flow at a higher level than the surrounding land they are enclosed by embankments, called dykes. Along the wind-swept North Sea coast and its island-fringe stretch sand dunes varying in elevation from 30 to 150 feet. In places where the dunes are low, dykes of earth and stones, or ferro-concrete, have been built to protect the low-lying land behind from the inroads of the sea.

Behind these dunes stretches the *polder* country, where thousands of acres of marsh-land have been reclaimed by building dykes and cutting canals. The reclamation of the Zuider Zee is still proceeding: so far three polders have been reclaimed. Under the *Delta Plan*, dams carrying roads are being built across the mouths of the Rhine to link deltaic islands with the mainland.

In Holland, owing to the dense population, land is extremely valuable and intensively cultivated. Some of the polders are sown with rye, oats, wheat, and barley; others planted with potatoes, sugar-beet, mustard, and flax. But the greater part of the polder land consists of pasture on which some 3,000,000 cattle are grazed. Dairying is one of the leading industries. The production of butter, cheese, and condensed milk is important, as also is the manufacture of margarine, in the preparation of which milk is mixed with vegetable oils, these being obtained from the East Indies. *Groningen* is one of the principal butter-collecting centres; *Alkmaar* and *Edam* are famous for their cheeses. In the district south of *The Hague*, which is the seat of the government, fruit, vegetables, and flowers are raised under glass; round *Haarlem*, to the north, are the famous bulb-fields.

On the *South Limburg Coal-field* mining has developed in recent years, and in this area are industries associated with the manufacture of chemicals, cement, glass, and paper. In the west, woollen goods are made at *Tilburg*, rayon at *Breda*, and cotton and linen goods, and sacks (imported jute) around *Overijssel*.

Amsterdam (870,000), on the shallow *Zuider Zee*, is, like many cities in Holland, built on reclaimed land. It is linked by the *North Sea Ship Canal* with the sea at *IJmuiden*, and with the *Rhine* by a 45-mile deep-water canal, opened in May 1952. Its imports include rubber, vegetable oils, tobacco, and cocoa from *Indonesia*; cane-sugar and coffee from *Dutch Guiana*; diamonds from *South Africa*. Part of this produce is manufactured in *Amsterdam*, part is re-exported. The city has large sugar-refineries, and shares with *Antwerp* the premier position in the diamond-cutting industry. *Rotterdam* (726,000), on the river *Lek*, a mouth of the *Rhine*, is also linked with the *North Sea* by a ship-canal. It has big shipyards and oil-refineries. It is the second busiest port in

FIG. 129. Reclamation in the *Zuider Zee*.

the world. Its position at the mouth of the Rhine has given it a great transit trade. The bulk of the goods brought to Rotterdam by sea-going vessels are transhipped to motor barges that carry them up the Rhine to Western Germany, Eastern France, and

Switzerland. To cope with increasing trade, due partly to the Common Market, a new oil-port, called *Europort*, has been built at the mouth of the waterway linking Rotterdam with the North Sea; and from it oil is pumped through a 185-mile

FIG. 130.

pipeline to refineries in Western Germany. Opposite Europort is the Hook of Holland, which, like Flushing, on an island at the mouth of the Schelde, is a packet station.

The maritime position of Holland, athwart one of the main arteries of Europe, gave her people great opportunities for trade, and contributed to their expansion overseas, where they built up a big colonial Empire. They still retain colonies in the Caribbean area, but their former possessions in the East Indies and New Guinea now form part of the Republic of Indonesia.

EXERCISES

1. How do you account for the fact that Belgium and Holland are two of the most densely peopled countries in Europe?
2. Divide Belgium into natural regions. Describe *one* of these regions with reference to (a) its climate, (b) its soils, and (c) its human activities.
3. Describe the position of (a) Antwerp and (b) Rotterdam, illustrating your answers by sketch maps. Which of these two ports do you consider is the more advantageously placed? Compare their trade.
4. Describe the methods by which the Dutch have reclaimed a large proportion of their country from the sea. In what *area* have extensive reclamation schemes recently been successfully completed?

SWITZERLAND: A BUFFER STATE

Placed in the heart of Europe, Switzerland has no seaboard, but her position at the crossing-place of transcontinental routes gives her access to three of the chief European countries as well as to the Danube Lands. A buffer state, she has preserved her independence. Yet her people have no common racial origin, neither have they one

common language. Those in the west and south-west are French-speaking; those in the north and centre talk German; around the heads of Lake Maggiore and Lake Lugano, Italian is the usual tongue; while in the Upper Rhine valley Romansch, a dialect derived from Latin, is used. The majority of the educated people are, however, bilingual, and many speak three languages.

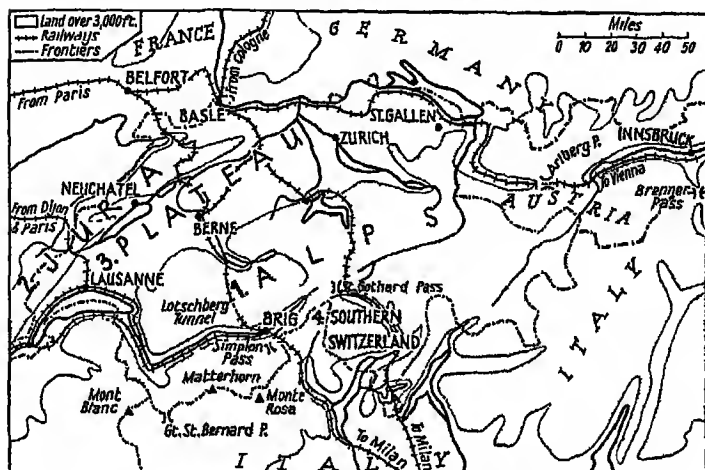

FIG. 131. Switzerland: Natural Regions.

Four Natural Regions may be distinguished: (1) the Alps, (2) the Jura, (3) the Plateau, lying between these two areas, and (4) Southern Switzerland (Ticino).

(1) **The Alps.** About a quarter of the Alps, which extend in a semi-circle from the Gulf of Genoa to the middle Danube Plain, lies in Switzerland. The Alpine fold-ranges are separated by longitudinal valleys traversed by numerous rivers. Some of the longest streams in Europe rise in the Alps. Among them are the Rhine flowing into the North Sea, the Rhone falling into the Mediterranean, and the Po running eastward to the Adriatic. Though the headwaters of the Danube are in the Black Forest Range, the Inn and other of its tributaries have their sources in the Alps. Roads and railways from Central Europe to the Mediterranean wind up the Alpine valleys to the passes. The roads cross the passes: many of the railways tunnel

underneath or near the most important ones. The chief of these passes are the *Mont Cenis*,¹ which leads from France to Italy; the *Great* and *Little St. Bernard*, west of the Pennine Alps, little used at the present time; the *Simplon*;¹ the *St. Gotthard*;¹ and the *Brenner Pass*, on the Austro-Italian frontier, crossed by the railway from Innsbruck (Austria) to Verona (Italy). The *Arlberg Pass* (Austria) forms a channel of communication between the valleys of the Rhine and the Inn.

The Alps, rising to nearly 16,000 feet, contain most of the highest peaks in Europe. Mont Blanc (15,800 feet) towers above the Franco-Italian frontier; somewhat to the east the Matterhorn (14,700 feet) and Mont Rosa (15,217 feet) rise high above the ridges of the Pennine Alps, whose snow-clad crests here form the frontier between Switzerland and Italy.

Among these peaks and ranges lie great snowfields from which glaciers, such as the Aletsch glacier in the Bernese Oberland, move slowly—from 50 to 350 feet a year—down the valleys. In the Ice Age, glaciers, far larger than any in Switzerland to-day, filled the Alpine valleys and carried down morainic material which they spread over the lower lands. As such glaciers travelled down the river valleys they *over-deepened* them, forming trough-like U-shaped depressions. Such glaciated valleys have flat floors bordered on either side by steep cliffs, above which rise the more gradual slopes of the original V-shaped river valley. From these gently graded side valleys, known as *hanging valleys*, streams often descend by waterfalls to the main U-shaped valley below. Such streams furnish power to generate electricity used in Alpine villages, by funicular railways, and in factories. The hanging valleys are covered with glacial debris which forms a fertile soil, clad with rich pastures, called *alps*. In winter these alps are covered with snow, but in spring and summer many cattle are driven up from the lower lands to graze on their well-watered slopes. Thus dairying, associated with the making of cheese, condensed milk, and milk chocolate, is important in the Alpine region. The hotel industry brings much wealth to Switzerland. Both in summer and winter tourists visit the Alps, while seekers after health stay at high resorts, such as Davos (5,121 feet) and Arosa (6,000 feet), to benefit by the pure, dust-free, and invigorating air and the powerful sunshine.

¹ Railway tunnels have been constructed under or near these passes.

(2) **The Jura**, which extend from the valley of the middle Rhone to the Rhine, do not exceed 5,000 feet. As in the Alps, the fold-ranges are separated by longitudinal valleys between which, however, communication is established by transverse river gaps (called *chuses*), like those followed by the railways from Dijon (*a*) via Neuchâtel to Berne, and (*b*) to Lausanne. The broad valley floors are clad with meadows, the steeper slopes with pinewoods above which rise upland pastures. Dairying and forestry are important. Watch-making is carried on at Chaux-de-Fonds, the largest town in the region.

(3) **The Plateau** lies between the Alps and the Jura, which converge towards the lower end of Lake Geneva. From this lake the wedge-shaped upland stretches north-eastward, growing broader as it approaches Lake Constance and the Rhine. With an elevation of from 1,200 to 2,400 feet, it is an undulating region with many rounded hills of morainic material, but with few extensive stretches of level land. The greater part of the Plateau lies in the basin of the Aar, which, after descending from the Bernese Oberland, carries the drainage of Lakes Neuchâtel, Lucerne, and Zürich to the Rhine.

Of the 4 million inhabitants of Switzerland the majority live on the Plateau. Agriculture is confined mainly to growing crops, like wheat, rye, and potatoes, required for home consumption. It is interesting to note that though one-quarter of Switzerland is forested, so great is the demand for wood, both for house-building and fuel, that timber has to be imported. Owing to its central position *Berne* (160,000) the capital, is a great railway junction, as too is *Basle* (200,000). The latter town is a focus of routes coming up the Rhine valley from Cologne; westward from Vienna via the Arlberg tunnel; and east from Paris by way of the Burgundian Gate. From *Basle* the railway through Lucerne makes for the St. Gotthard tunnel, whence it descends by the Ticino valley, and crossing Lake Lugano passes through Como (Italy) to Milan. The line from Paris and Dijon, after passing through Lausanne, continues up the Rhone valley to Brig, passes through the Simplon tunnel, and descends by way of the Toce valley and Lake Maggiore to Milan. After leaving Berne another railway ascends the Aar valley to Lake Thun and reaches the Simplon line by way of the Lotschberg tunnel.

All the largest towns in Switzerland are situated on the Plateau and

nearly all are engaged in some form of manufacture. Switzerland lacks coal and other minerals, but is exceptionally rich in hydro-electric power, which is used for industrial and domestic purposes, and by the railways, nearly all of which are electrified. Owing to her situation most of the raw materials required for Swiss manufactures have to be imported, often from a considerable distance, and, in the case of those obtained from overseas, through foreign ports. Thus the Swiss, like the people of South-West Germany, concentrate on the manufacture of goods requiring relatively little raw material, but much skilled labour, for their production. *Geneva* (168,000), at the south end of Lake Geneva, was the seat of the former *League*

FOREIGN TRADE OF SWITZERLAND

FIG. 132.

of Nations. It makes watches, clocks, scientific instruments, and jewellery, while similar goods are also manufactured at Neuchâtel and Berne. Raw silk, imported mainly from Italy via the St. Gotthard route, is manufactured at *Zürich* (430,000), the largest town in Switzerland, Basle, and other smaller centres on this commercial highway. *St. Gallen*, some distance south of Lake Constance, manufactures lace, embroidery, and fine cotton goods. *Basle* is an exception to the general rule regarding Swiss manufactures, for, owing to its situation on the Rhine, it can import cheaply by water the bulky and heavy raw materials required for its chemical and dye-stuff industries.

(4) **Southern Switzerland** (consisting of the canton of Ticino), stretching from the southern slopes of the Alps to the heads of Lake Maggiore and Lake Lugano, differs greatly from the rest of the country. Owing to their latitude, their sunny skies, and the fact that they are sheltered by the Alps from the cold north winds, the southward-facing valleys have an exceptionally genial climate, and their products (which include vines and warm temperate fruits) resemble those of the adjacent lake district of Northern Italy. Both Lugano and Locarno are popular lake-side watering-places.

EXERCISES

1. How do you account for the fact that Switzerland specializes in the manufacture of goods requiring comparatively little raw material, but needing skilled labour, and of considerable value in proportion to their bulk? Name four such manufactured goods, stating in each case (i) the chief centres of production, and (ii) one country supplying the necessary raw materials.

2. Draw a sketch-map of the Alps showing the principal passes. Insert the chief railway lines and in each case mark and name one important town on either side of the Alps.

3. (a) Draw a contour map, representing a typical U-shaped valley in the Alps. On your map mark, by the letter P, the probable site of a power station. (b) Contrast the life led by the inhabitants in summer with that during winter.

EUROPEAN ECONOMIC GROUPS

The European Economic Community (The Common Market) is an association of six countries (see p. 191) whose aim is to abolish all trade restrictions between themselves and to set up a common tariff wall against other countries.

The European Free Trade Association (EFTA) consists of seven countries (Austria, Denmark, Norway, Portugal, Sweden, Switzerland, and the United Kingdom) pledged to abolish trade restrictions between themselves, though each member retains freedom to pursue its own trade policy towards countries outside the group.

In 1961 the United Kingdom and certain other members of EFTA started negotiations with the European Economic Community with a view to joining the Common Market.

CHAPTER XIV

THE BALTIC LANDS AND THEIR MARGINS

DENMARK

DENMARK is about twice the size of Wales. It comprises most of the Jutland Peninsula and a number of islands at the mouth of the Baltic. Except for the rocky island of Bornholm, in the Baltic, the country is flat, or undulating, and forms part of the Great European Plain. The west coast of Jutland has few good harbours. It is fringed by sand-dunes backed by barren heaths. In recent times much land in this district has been reclaimed by planting pine-woods and hedges to prevent the sand from blowing farther inland, and by draining and fertilizing the soil. Denmark lacks coal, iron, and water-power, but her people by adopting scientific farming methods have made good use of their limited resources.

Little more than half a century ago mixed farming was the rule in Denmark. But the Danish farmers found they were losing their markets owing to the competition of cereals and other produce from the New World. So they turned their attention to dairying and the rearing of pigs and poultry, thus producing butter, bacon, and eggs, the bulk of which found a market amidst the rapidly growing population of industrial England. Marshes and moorlands were reclaimed, impoverished soils improved by fertilization, clover, roots, oats, and other fodder crops were sown, and herds were improved by the introduction of pedigree stock. At the same time the farmers, though retaining the ownership of their small farms, adopted co-operative methods. They joined together to establish dairies, to purchase fodder, fertilizers, tools, machinery, pedigree stock, and to transport and market their produce. By-products were utilized, e.g. skim milk was used to feed pigs, and regular inspection and the grading of produce ensured that high standards were maintained. Thus did the Danes acquire a reputation for their dairy produce, the bulk of which is shipped to England.

Denmark has valuable fisheries. She sends ships to the North Sea, but many cod, plaice, and mackerel are caught in the Kattegat. Young plaice from the North Sea are reared on a vast scale in the

Lijm Fiord. Esbjerg, the chief fish market, is a packet station for Harwich, the journey taking 19 hours.

One-fourth of Denmark's $4\frac{1}{2}$ million inhabitants live in the capital, *Copenhagen*, and its suburbs. Standing on the Sound, at the entrance to the Baltic, it has a commanding situation. It is a great entrepôt port, from which produce is dispatched to all parts of Central and Northern Europe by way of train ferries which provide direct communication with Stockholm via Malmo, Lübeck, and Hamburg. Its industries include distilling, brewing, sugar-refining, and the making of porcelain. Next in size to the capital are *Aarhus*, on the east coast of Jutland, and *Odense*, in Fyen.

Denmark is closely allied by ties of race, language, and culture to Norway and Sweden, and from time to time the three countries have formed, in whole or part, one kingdom. In the

days of the Vikings Norway was the chief state; in the Middle Ages Denmark, best placed for trade, took the lead; but in the seventeenth century Sweden—owing mainly, however, to historical rather than geographical causes—was predominant.

The *Faroe Islands* (540 square miles), placed midway between Norway, Scotland, and Iceland, are part of Denmark. *Greenland* is the only colonial possession.

Iceland (40,000 square miles). Formerly united to Denmark by common allegiance to the same king, Iceland became a republic in 1944. Much of the island is unproductive, but it is interesting on account of its glaciers, active volcanoes (Hekla), and fiords. Fishing and sheep farming are the chief occupations.

FIG. 133. Denmark.

EXERCISES

1. Give a reasoned account of the dairy industry of Denmark.
2. Illustrating your answer by a sketch map, describe the situation of Copenhagen and discuss the geographical causes that have contributed to its importance.

FIG. 134. Norway, Sweden, and Denmark.

SCANDINAVIA—NORWAY AND SWEDEN

Scandinavia is divided politically into Norway and Sweden. The greater part of the peninsula consists of a lofty plateau composed of ancient and much-denuded rocks that extend into Finland. Only in Southern Sweden is there a considerable lowland area, which here forms a detached portion of the Great European Plain. Greatest of all agents which have worn away the surface was ice, which during the Ice Age covered the whole peninsula. The highlands rise steeply from the west coast, but slope gradually in wide terraces to the Baltic. They are highest and widest in the south-west, where they reach their greatest elevations in the Jotun Fjeld and the Hardanger Fjeld—wild rock-strewn wastes amid whose peaks lie snow-fields and glaciers. From the main watershed, which lies close to the west coast, short, swift streams descend to the Atlantic, while longer ones flow south-east to the Baltic. Many of the latter expand into lakes and form numerous falls which, like the Trollhättan Falls on the Gota river, are harnessed for electric power.

The precipitous west coast is fringed with countless islands and indented with steep-sided fiords, some of which, like the Sogne fiord, extend into the plateau for more than 100 miles. The Swedish coast is lower and much less broken than that of Norway.

Climate. The prevailing south-west winds drive the warm water of the North Atlantic Drift along the west coast, causing the climate to be very mild. On the other hand, the east coast lands, facing the shallow and almost land-locked Baltic, have a more extreme climate. The summers are warmer, but the winters are much colder and in the north-east the harbours are ice-bound, as the Gulf of Bothnia is blocked with ice for seven months in the year. The south-west winds impinging on the steep mountain wall cause a heavy rainfall along the western side of the peninsula; but the east, lying in the rain-shadow of the mountains, is relatively dry. Compare the annual rainfall at Bergen, 81 inches, with that at Härnösand, on the east coast, 23 inches; and at Skjåk, in the sheltered interior, which has only 10 inches.

NORWAY

Though the area of Norway is approximately equal to that of the British Isles, yet her population scarcely exceeds $3\frac{1}{2}$ millions. The greater part of the country is mountainous, nearly three-quarters being unproductive. About one-fifth is covered with coniferous forests, and lumbering is an important industry, especially in the districts round Oslo. Out of every

FIG. 135. Comparative Utilization of Land in Norway.

100 acres less than 4 are suitable for cultivation and pasturage. Most farms are small and nearly half are under 3 acres. Many are placed at the heads of the fiords, on narrow strips of land at the base of the mountains, or in the lowland districts around Oslo fiord. Hay, potatoes, barley, and oats are the chief crops, but in most areas there is insufficient warmth and sunshine to ripen wheat. In spring cattle are driven to the upland pastures, where they remain until autumn, returning in winter to the low-

lands, where they are housed in barns.

With a barren interior and a richly indented coast the Norwegians have become a nation of seafarers. Their mercantile marine, ranking third after that of Britain and the United States, includes a fleet of oil-tankers. Fishing is one of the leading industries. From *Bergen* and *Trondheim* steel ships go out to seek herring and cod; while some visit the Antarctic whaling grounds, for of all countries Norway ranks first in the whaling industry. Hammerfest, within the Arctic Circle, is a leading cod-fishing centre.

Norway's relative lack of minerals is compensated by her vast supplies of water-power. Much hydro-electric power is used by pulp and paper-mills, and still more by her electro-chemical industries, which include extracting nitrogen from the air for use in the manufacture of fertilizers.

Railways, partly electrified, connect *Oslo* (450,000), the capital, with *Bergen*, *Stavanger* and *Trondheim*, and with Swedish lines, but

15 MAN AND NATURE IN SCANDINAVIA

(Above) Stockholm, the capital of Sweden, which is mainly built on two groups of islands: one at the entrance to Lake Mälar and the other in an arm of the Baltic. The oldest part of the city stands on the main island. Most of the fine public buildings are constructed of granite (see p. 210). (Below) The Geiranger Fjord, one of the many fiords that pierce Norway's 12,000 miles of precipitous, island-fringed coastline. With her rugged mountains, rivers, lakes, and fiords, Norway has little land available for cultivation, and most of the arable ground lies in narrow strips along the rivers or at the heads of the fiords.

16 A DANISH DAIRY FARM—THE MOSCOW-VOLGA CANAL

(Above) A Danish dairy farm. The farmsteads were originally built in this shape to provide protection against wild animals (see p. 204). (Below) The Moscow-Volga Canal, opened in July 1937. Moscow is now an inland port connected with the Baltic, White, Black, and Caspian Seas.

owing to the mountainous nature of the country communications are carried on principally by water, road, and air.

Norway's sovereignty over *Svalbard* (Spitzbergen), which has rich supplies of coal, was recognized in 1920.

SWEDEN

Sweden, unlike Norway, contains a considerable proportion of lowland. Southern Sweden is one great agricultural region where villages lie amidst fields of sugar-beet, wheat, oats, and potatoes, interspersed with woods of oak, beech, and other broad-leaved trees. Nearly half the kingdom is clad with forests of pine and spruce. Lumbering is important, especially in Central and Northern Sweden. In spring the rivers are alive with timber floating down to the saw-, pulp-, and paper-mills which are usually placed at or near their mouths to facilitate export. Norrköping is one of the leading centres of the paper industry; Jönköping, at the southern end of Lake Vätter, is famous for matches.

Sweden is rich in *iron ore* of a remarkably high quality.

The Dannemora mines lie 60 miles north of Stockholm. From the Gellivare and Kiruna mines, farther north, much ore is exported from the Norwegian port of Narvik, which, unlike Lulea, the Swedish terminus of the line serving this district, is ice-free throughout the year.

Like her neighbour, Sweden lacks coal. She owes her industrial progress to the development of her hydro-electric power, which is used in her saw-, pulp-, and paper-mills; iron, steel, and electrical works; and in factories, e.g. woollen mills at Norrköping.

FIG. 136. Comparative Utilization of Land in Sweden.

FIG. 137.

Stockholm (795,000), the capital, on Lake Malar, has shipbuilding, engineering, pottery, and chemical industries. It is connected by rail with all parts of Sweden. Next in size to the capital is *Göteborg* (390,000), the chief port of Sweden, at the mouth of the Göta River. The Göta Canal, now used mainly for tourist traffic, links this port, by way of Lakes Vänern and Vättern, with the Baltic. *Malmö*, on the Sound, is connected by train ferry with Copenhagen.

EXERCISE

1. Compare Norway with Sweden under the following headings: (a) relief, (b) climate, (c) products, (d) human activities.

FINLAND

Finland stretches from the Gulf of Finland to the Arctic Ocean. Though comparable in size to the British Isles its population is little more than $4\frac{1}{2}$ millions. More than one-tenth of the country consists of rivers, swamps, and lakes which range in size from Lake Saima to tiny lakelets. Three-quarters of the land-surface is forested. The north is a tundra region scantily peopled by Lapp tribes with herds of reindeer.

Structurally Finland is a low plateau. It forms part of the Baltic Shield, an ancient crust-block, which on the east extends to the depression running from the head of the Gulf of Finland through Lakes Ladoga and Onega to the White Sea, and on the west sinks beneath the Gulf of Bothnia to reappear in eastern Sweden. The bedrock, everywhere near the surface, is scarred by the marks of former glaciers, which (i) rounded the hills, (ii) scooped out rock basins now filled by innumerable lakes connected by short, swift streams on which rapids are frequent, and (iii) deposited masses of debris often in the form of low ridges, which provide sites for villages and are utilized by roads and railways in order to avoid the swampy ground. The Salpausselkä, a terminal moraine running from Hanko to Lake Ladoga, backs the coastal plain which fronts the Gulf of Finland. In their passage across this ridge the rivers draining the lakes of southern Finland to the Gulf have cut rapids, whose waters are frequently harnessed for hydro-power. Such power is of great importance in a country that lacks coal.

Though a considerable proportion of Finland lies within the Arctic Circle, its climate is milder than that of most countries in similar latitudes, partly on account of the low elevation, partly because of the presence of large bodies of water which moderate the temperature of surrounding areas. But though the summer is warm even in the north, the long winter everywhere means snow and temperatures well below freezing-point.

Agriculture gives employment to more than half the working population, despite the fact that only 8 per cent. of the land is suited to cultivation. Many farms are situated in clearings beside the lakes. The chief crops are roots, hardy cereals such as rye and oats, and hay, which is stored in big barns for winter fodder. Much land is devoted to dairying, which is run on co-operative lines. As forests cover so large an area lumbering is important.

Timber is floated down the waterways; transport has been facilitated by cutting canals to avoid the rapids. Wood is widely used for fuel and for building houses. Sawn timber, pit-props, wood-pulp, and paper comprise about 80 per cent. of the country's exports, the bulk being shipped through *Kotka*, on the Gulf of Finland, which is, however, ice-bound in winter.

Ice-breakers are used to keep open the harbour of *Helsinki* (Helsingfors), the capital, on the Gulf of Finland, which manufactures textiles and metal goods; and that of *Turku* (Åbo), which exports

FIG. 138. Finland and its margins.

cattle, dairy produce, and timber, and manufactures paper, cotton goods, and margarine. Railways run from Helsinki and Turku to *Tampere*, the largest inland town, which uses local hydro-electric power in its saw- and paper-mills and cotton factories. Northward the line passes through Oulu to Tornio, at the head of the Gulf of Bothnia, where there are connexions with both the Swedish and Russian railway systems.

It is generally accepted that the Finns are of Mongolian origin. For more than five centuries they were ruled by the Swedes, many of whom settled in the coastal belt. During this period a new Swedo-Finnish people arose, who derived much of their language and culture from Sweden. In 1809, Sweden ceded Finland to Russia, who ruled the country until 1917 when it became a Republic. In 1944, as a result of unsuccessful conflict with Russia, Finland ceded territory to that country, including the ice-free port of Petsamo, on the Arctic, and the timber port of Viborg (Viipuri), on the Gulf of Finland.

EXERCISE

1. Write an account of Finland under: (a) physical features, (b) climate, (c) natural vegetation and products, (d) chief towns and communications.

THE UNION OF SOVIET SOCIALIST REPUBLICS (U.S.S.R.)

RUSSIA

The European portion of the U.S.S.R. comprises half of Europe. The Russian Plain stretches from the White Sea south to the Caspian, the Caucasus, the Black Sea, and the lower Danube; and from the eastern frontier of Poland it extends to the Urals. The plain, floored with horizontal sedimentary strata and covered in the north with morainic deposits, is relatively level, rising in low swellings rather than ridges. Chief of these uplands is the belt running from the Sea of Azov northward to the Valdai Hills, where it reaches a height of somewhat over 1,000 feet. From this upland area another, but rather broken, belt runs north-eastward to the Urals.

Many of the rivers have cut their way deep below the general level of the plain; and those which, like the Volga, flow south usually have a high right bank and a low left bank. The Volga, the longest river in Europe, rises in the Valdai Hills and flows into the Caspian Sea through a huge delta. Among its chief tributaries are the Oka which

enters it at Gorky, and the Kama which joins it south of Kazan. Near Volgograd, the Don approaches within 40 miles of the Volga. The Don, whose chief tributary is the Donetz, flows into the Sea of Azov. The Dnieper, the Dniester, and the Danube, which forms part of the Russian-Rumanian frontier, enter the Black Sea. The principal rivers entering the Baltic Sea are the Dvina flowing into the Gulf of Riga, and the Neva carrying the drainage of lakes Ladoga and Onega to the Gulf of Finland. These two lakes—the largest in Europe—are linked by the river Svir, now canalized to form part of the Stalin Canal, whose construction shortened the distance between the Baltic and White Seas by 2,160 miles. A branch of this canal, running from the southern end of Lake Onega to the Sheksna, a tributary of the Volga, provides through communication with the latter river and thus with the Caspian Sea. The building of canals linking the larger rivers has greatly increased the usefulness of Russia's inland waterways. The completion of the Don-Volga Canal has made it possible for ships to travel not only between the Baltic and White Seas and the Caspian, but also by river and canal to the Sea of Azov and the Black Sea. Unfortunately all these waterways are frozen in winter for periods ranging from three months in the south to six in the north.

Most of Russia has a continental climate with extremes of heat and cold. In winter, with the exception of the Crimean Peninsula, which has the mildest climate in the republic, the whole country has a temperature below freezing-point. The farther one travels north-east, away from the Atlantic, the colder it becomes. Compare the January temperatures at Kiev (21° F.), Moscow (12° F.), and Kazan (7° F.). In summer, broadly speaking, temperatures decrease from south to north, but the eastern part of the country is somewhat warmer than the west. Over most of Russia the mean annual rainfall is about 20 inches, but it is less in the north, owing to the low temperatures, and in the south-east (round the north and east of the Caspian Sea), as the prevailing winds blow over the land.

Natural Regions. As the climate and configuration are similar over vast areas, so, too, is the natural vegetation, which depends mainly on climatic conditions. It should, however, be clearly grasped that in many districts the natural vegetation has been modified by man, and that the different zones merge gradually into each other. In no

other country does the natural vegetation correspond more closely to the Natural Regions.

(1) **The Tundra** consists of a relatively narrow belt stretching along the coast-lands bordering the Arctic. The climatic conditions are too severe for trees, and vegetation is mainly confined to mosses and lichens on which feed the reindeer kept by nomadic Lapps

and Samoyedes. The ports of Murmansk, connected by rail with Leningrad, and Petsamo, are usually ice-free in winter owing to the influence of the warm North Atlantic Drift.

(2) **The Coniferous Forests** stretch from the tundra southward to a line running from the head of the Gulf of Finland to the confluence of the Volga and the Kama. Of the 40 per cent. of European Russia which is forested, the greater part is covered with pine and larch, and other coniferous trees. Lumbering is being developed. In summer timber is floated down the Pechora to the Arctic, and down the northern Dvina to

FIG. 139. European Russia : Natural Regions.

saw-mills at Archangel. On cleared lands potatoes, rye, and oats are grown. *Archangel*, some miles up the Dvina, a naval base and port for the White Sea fisheries, builds ships. Its harbour is closed by ice in winter. It is linked by the Stalin Canal with *Leningrad* (3,200,000). This city has engineering, chemical, and electrical works, and textile factories, but, like the timber port of *Viborg* to the north-west, it is ice-bound in winter.

(3) **The Deciduous Forest Belt.** On the south the cold forests merge into the deciduous forests which stretch across European Russia to the Baltic. The southern margin of this region is marked by a line running from Kazan, on the Volga, south-west through Kiev and thence to the Carpathian foothills. In the transitional zone between the coniferous and deciduous forests, conifers mingle with

oaks and other broad-leaved trees. Besides including the heart of European Russia, this region embraces the Baltic Soviet Republics of Estonia, Latvia, and Lithuania; part of the former German province of East Prussia including Königsberg (Kaliningrad); and a belt of territory ceded by Poland to the U.S.S.R. in 1945.

Generally speaking, the Deciduous Forest Region is more densely

FIG. 140. The Site of Moscow.

settled than the Cold Forests, though in certain areas, notably the Pripet (Pinsk) Marshes—the greatest marshland in Europe—the density of population is extremely low. The forests provide a valuable store of timber as well as raw material for the manufacture of paper and artificial silk. Much land has, however, been cleared for cultivation. The climate restricts agriculture to quickly maturing crops, such as rye (the chief bread-crop), oats, barley, potatoes, sugar-beet, flax, and hemp. Many cattle and pigs are reared and much land is devoted to dairying, especially in Estonia, Latvia, and Lithuania.

Moscow (5,000,000), the capital of the U.S.S.R., placed on high ground above the Moskva, in the centre of the plain, is a focus of routes by rail, water, and air. The Moscow-Volga Canal, opened in

July 1937, by diverting part of the waters of the Volga into the Moskva (Fig. 140), has made the latter a navigable waterway and also increased the supply of water available for Moscow's requirements. The city is now an inland port connected with the Baltic, White, Black, and Caspian Seas. Moscow's engineering shops and textile factories are supplied with coal from the *Tula Coal-field* to the south. Important cities standing where railways cross the Volga are *Gorky* (Nijni Novgorod), which manufactures motor-cars; *Kazan*; *Kuibishev* (Samara), a flour-milling centre; and *Saratov*, which refines oil shipped up the Volga.

The area ceded by Poland to the U.S.S.R. includes the oil-fields of Eastern Galicia, which extend along the Carpathian foothills. To the north-east is *Lemberg* (Lwow), an important flour-milling centre. Farther north, flax and potatoes are widely grown around *Wilno* (200,000), which is noted for its distilleries. The chief Baltic ports are *Reval* (Tallinn), the capital of the Soviet Republic of Estonia, standing near the mouth of the Gulf of Finland; *Riga* (565,000), the capital of Latvia, situated some miles up the Dvina, which is an important timber-exporting port; *Menel*, at the entrance to the Kurisches Haff, the principal outlet for Lithuania; and *Kaliningrad* (Konigsberg), which exports timber and flax.

(4) **The Steppes**, which extend from the deciduous forest belt, through the *Ukraine*, to the Black Sea, resemble the prairies of North America. The Black Earth Lands, their most fertile portion, lie mainly in the Ukraine, whose tractor-ploughed collective farms produce 20 per cent. of Russia's wheat and vast quantities of barley, oats, and sugar-beet. Of the 208 million people in the U.S.S.R. 42 million live in the Ukraine, the chief industrial as well as the leading agricultural area in the U.S.S.R. The *Donetz Basin*, with the *Krivoi Rog iron-field*, accounts for 60 per cent. of the coal, 60 per cent. of the iron ore, 50 per cent. of the steel, and 70 per cent. of the aluminium produced in the U.S.S.R. There is a huge hydro-power plant at *Zaporozhye*, where a dam has been built across the Dnieper. *Kiev*, the capital of the Ukraine, rose up at the junction of the forests and the steppes. Other cities in the Ukraine, or on its margins, are *Dnepropetrovsk*; *Kharkov*, making tractors and machine tools; *Mariupol*, on the Sea of Azov, and *Volgograd* (Stalingrad), on the Volga, both iron and steel centres; and *Odessa*, which like *Kherson*, on the Dnieper, and *Rostov-on-Don*, is a grain port.

(5) **The Steppe-Desert region**, a depression north and east of the Caspian, provides rough grazing. From *Astrakhan*, the centre of

FIG. 141. European Russia: Waterways, Coal-fields, and Oil-fields.

the sturgeon fisheries of the Caspian, oil is shipped up the Volga into the heart of Russia; while from *Chapayev* it is piped from the neighbouring Emba field to the Urals.

(6) **The Caucasus Region.** The Caucasus fold-ranges (Elbruz, 18,470 ft.), richly timbered on their lower slopes, contain deposits of iron, coal, copper, lead, zinc, and steel-hardening metals, such as nickel and manganese. The U.S.S.R. produces 10 per cent. of the world's oil, no less than 75 per cent. of Russia's supply coming from the *Baku* wells, whence the bulk is piped to *Batum*, on the Black Sea. From the *Grozny* gushers oil is piped to the refining centre of *Armavir*, and thence (1) to *Tuapse*, on the Black Sea, and (2) through *Rostov-on-Don* to the *Donetz* Basin.

(7) **The Urals** are rich in coal, iron, copper, nickel, chrome, and oil, all of which, since 1920, have been worked on an increasing scale in accordance with the policy of developing fresh industrial centres in the Urals and eastward. So great is the demand for coal that Ural supplies are supplemented by others from the *Karaganda* and *Kuznetsk* coal basins. *Magnitogorsk*, and its still more recent rival *Nizhni Tagil*, are among the leading iron and steel centres in the U.S.S.R. The latter town also manufactures chemicals, and, like *Sverdlovsk*, machine tools. *Perm* is a mining centre. *Chelyabinsk* builds aircraft and tractors. Nickel and chrome are mined at *Orsk*, which refines oil from the *Emba* field (north-east of the Caspian). *Ufa* is the main refining centre on the Ural oilfield, from which a pipeline is now being laid down to East Germany.

The Expansion of Russia. The absence of physical barriers in European Russia has played a great part in moulding Russian history. But the vast extent of the country has hindered development.

In the ninth century the chief centres of European Russia were *Novgorod*, on the way from the Baltic to the Volga, and *Kiev*, in the Ukraine. Both these towns lie on the easiest route from the Black Sea to the Baltic, which runs east of the Carpathians and the Pinsk marshes. In the twelfth century Mongol invaders from Central Asia spread from *Kazan* over the steppes, but in the fifteenth century *Ivan the Great* defeated the Mongols and made *Moscow*, in the centre of the plain, the capital of *Moscovy*. Though transport was difficult in summer, in winter it was relatively easy over the hard frozen ground, and thus *Ivan* extended his kingdom northward to the White Sea. In the sixteenth century the Mongols were driven out of European Russia, whose boundaries were extended south to the Black and Caspian Seas, and east to *Siberia*. The founding of

St. Petersburg (Leningrad) by Peter the Great in 1702 marked the beginning of Russian expansion along the eastern shores of the Baltic. The extension to the Pacific in the nineteenth century was completed by building the Trans-Siberian Railway.

After the Revolution in 1917, when Russia became a Union of Soviet Socialist Republics (U.S.S.R.), Finland, Estonia, Latvia, and Lithuania became independent republics. In 1940 these territories, except Finland, were reincorporated in Russia. After the Second World War, Russia extended her frontiers westward to include (i) territory in Eastern Poland, (ii) part of East Prussia, (iii) part of Rumania, (iv) part of Finland, and (v) Ruthenia, inhabited mainly by Russian-speaking peoples, ceded to her by Czechoslovakia.

EXERCISES

1. Draw a sketch map of European Russia showing the chief natural regions. Give a description of *one* of the more important regions under the headings: Relief, Drainage, Climate, Crops, and Towns.
2. Draw sketch maps of Moscow, Leningrad, and Odessa to show how their growth has been influenced by their geographical position.
3. Describe the position and industries of (a) the Ukraine Industrial Area, and (b) the Southern Urals Industrial Area. In both cases give sketch maps.
4. Describe a steamer journey from the Caspian Sea to Moscow and thence to the Baltic Sea. Name probable cargoes carried from the Caspian to Moscow, and from Moscow to the Baltic.

POLAND

Stretching from the Carpathians to the Baltic, Poland lies athwart the Great European Plain midway between Germany and Russia. The absence of natural boundaries in the west and east has led to a considerable intermingling in these frontier zones. Hence no distinct racial or linguistic lines can be drawn between the Poles and either the Germans on the west, or the Russians on the east.

In the latter part of the eighteenth century Poland was partitioned between Russia, Prussia, and Austria, but after the First World War (1914-18) she became an independent Republic. But Polish freedom was short-lived. The outbreak of the Second World War saw Poland invaded by both Germany and Russia who divided the country between them. This Fourth Partition lasted until June 1941, when Germany attacked Russia and overran Russian-occupied Poland. By March 1945 the Russians had driven the Germans out

of Poland. The former eastern frontier of Poland was not, however, acceptable to Russia, who laid claim to a broad belt of territory in eastern Poland on the grounds that the majority of its inhabitants consisted of Russians and other non-Polish-speaking peoples. In return for ceding this eastern zone to Russia, Poland received as

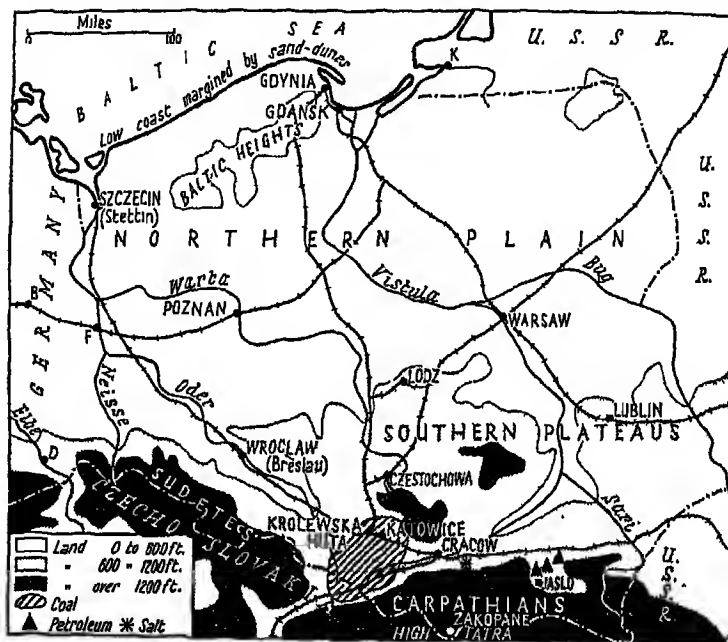

FIG. 142. Poland: Natural Regions.

compensation (i) part of East Prussia, (ii) Danzig, and (iii) an extension of territory in the west, which carried her frontier to the Oder and its tributary the Neisse, and included Stettin (Szczecin).

Poland has a continental *climate* which becomes more extreme towards the east. The summers are hot, but the winters are so severe that rivers and lakes are frozen for somewhat more than three months. At one time the greater part of the country was forest-clad, and even to-day over one-fifth is covered with forests of deciduous and coniferous trees, the latter predominating especially in sandy areas.

We may divide Poland into three Natural Regions : (1) the Carpathians, (2) the Southern Plateau, and (3) the Northern Plains.

(1) **The Carpathians.** Only a small portion of the Carpathians lie in Poland. These forested mountains, though forming a continuation of the Alps, are much lower than the latter ranges, and even in the High Tatra do not exceed 9,000 feet. They form a well-marked frontier separating the Poles from their neighbours in eastern Czechoslovakia (Slovakia).

(2) **The Southern Plateau,** though covering a much smaller area than the Northern Plain, is a more important region both on account of its rich and varied soils and its mineral wealth. The crops include wheat, sugar-beet, and flax. *Lublin*, on the north-eastern edge of the Plateau, is an important flour-milling centre. Many horses, too, are reared in this part of Poland, a country that has more horses per acre than any other except Denmark. This high proportion points to an absence of mechanical traction for farming purposes, and motor-cars and lorries for road transport.

Southern Poland is rich in minerals. Somewhat to the south of *Krakow* are salt-mines, and in the south-east of the plateau are deposits of potassium salts. In the coal basin of Upper Silesia, high-grade coal, relatively near the surface, is mined round *Krolewska Huta* (Konigshutte), and *Katowice*, whence coal is shipped by canal to the navigable Oder, and by rail to Gdynia and Gdansk for export. Local supplies of lead, zinc, and iron have given rise to metal industries mostly of the heavy type. *Czestochowa*, on the northern margin of the coal-field, manufactures cotton goods; *Wroclaw* (Breslau), a bridge-town on the Oder, is noted for woollens.

(3) **The Northern Plains,** comprising the greater part of the country, are watered by the Vistula, the Warta, and other right-bank tributaries of the Oder. These lowlands, which form part of the Great European Plain, extend westward into Germany and eastward into Russia.

The most extensive forest areas are in the north-east where they stretch across the frontier into Russia. Winter is the lumbering season. In spring, after the ice has melted, huge timber-rafts are floated down the river Vistula to saw-mills and lumber-yards

along its banks, and much timber is sent to Gdansk for export. The Vistula is linked with the Oder by a canal (running to the Netze), but apart from its use for floating timber this river, in common with most others in Poland, is now but little used for transport.

CHIEF EXPORTS OF POLAND	
Timber	■■■■■■■■■■
Coal and Coke	■■■■■■■■■■
Metal goods	■■■■■■■■■■
Rye and Barley	■■■■■■■■■■

FIG. 143.

Rye, potatoes, sugar-beet, and flax are the chief crops. The bulk of the rye is made into 'black' bread, one of the staple foods of the peasants in Eastern Europe.

The best potatoes are used for human consumption, but many are fed to pigs, of which there are some 7,000,000 in the country. Sugar-beet is grown mainly in the west. Cattle are bred for meat and dairy purposes, and, as in Denmark, the latter industry is associated with co-operative methods.

Warsaw, the capital, suffered enormous damage in the last war. Standing on the high left bank of the Vistula, it is an important route centre, railway junction, and airport. Routes go westward through *Poznan* (Posen), a metallurgical centre, to Berlin; southward to Krakow; eastward but north of the Pinsk marshes to Moscow; and north-east through Wilno to Leningrad. South-west of Warsaw is *Lodz* (600,000), great cotton and woollen manufacturing city.

Gdansk (Danzig), at the mouth of the Vistula, the natural outlet for Poland, exports timber, coal, and dairy produce. By the Treaty of Versailles (1919) it was constituted a Free City under the League of Nations, but after the Second World War it was transferred to Poland. *Gdynia* lies on the west of the Gulf of Danzig. *Szczecin* (Stettin) is the port for the Oder.

EXERCISES

1. Describe the position of the Upper Silesian coal basin. By what routes is the coal transported to the sea (a) by water, and (b) by rail? In each case name the port of export. Name the chief mining centres, and show their position on a sketch-map.
2. Divide Poland into three natural regions. Give a description of the most northerly of these regions under the headings: relief, drainage, climate, crops, and towns.
3. In normal times Germany does a large trade with Poland. Suggest as many reasons for this as you can, mentioning the chief goods exchanged.

GERMANY

As a result of her defeat in the Second World War, Germany lost some of her territory. It included that part of Germany lying east of the Oder and its tributary the Neisse (together with the port of Stettin), and part of East Prussia, which were transferred to Poland.

Meanwhile the rest of Germany was divided into British, French, American, and Russian zones of occupation. Berlin was likewise divided into four Allied sectors. In 1949, a *West German Federal Republic*, with its capital at Bonn, was set up in the British, French, and American zones; and an *East German Democratic Republic*, sponsored by Soviet Russia, was established in eastern Germany (see Fig. 148). At the same time Berlin was divided into Western Berlin, now a detached portion of the Federal Republic, and Eastern Berlin, the present capital of the East German Republic. Germany has a total area of 137,000 square miles, and a population of about 71 millions, of whom nearly three-quarters live in the Federal Republic.

The Federal Republic recovered so rapidly from the effects of the last war that today it is one of the leading industrial countries in Europe. Industrial expansion was stimulated by membership of the *European Coal and Steel Community*, set up in 1953, which abolished tariffs on coal, iron, and steel between its member countries, namely West Germany, France, Belgium, the Netherlands, Luxembourg, and Italy. It was the success of the Coal and Steel Community that led to the formation of the *Common Market* (see p. 191). Much of Western Germany's foreign trade is carried on with other Common Market countries, and the volume of such trade will increase.

Unlike Western Germany, the East German Republic is self-sufficient in foodstuffs. Its industrial output cannot, however, compare with that of its neighbour. Most of its foreign trade is with the U.S.S.R., and other east European states.

Climate and Vegetation. Though the prevailing winds over most of Germany blow from the south-west, they are neither so strong nor so constant as those of North-West Europe. The climate is transitional between the oceanic type of Western Europe and the

continental type of Russia. The summers are warm with moderate rainfall : the winters cold with heavy snowfalls in Eastern Germany. The increasing elevation from north to south has the effect of equalizing temperatures throughout the country. Thus at Berlin

FIG. 144. Germany: Natural Regions.

the mean January and July temperatures are 31° F. and 65° F. respectively, while at Munich the corresponding temperatures are 27° F. and 63° F.

In Germany, as in most parts of Europe, much forest, marsh, and moorland has been reclaimed for agriculture and pastoral land. But thanks to scientific afforestation more than one-quarter of the country is wooded, the most extensive areas being in the south. In the wetter and warmer areas beeches, oaks, and other deciduous trees thrive ; but pines are much more widely spread : they do well on indifferent soils and at relatively high elevations, while on account of their quicker growth they have a greater economic value.

Germany proper may be divided into three natural regions : (1) the Alpine Region ; (2) the Central Uplands, including the Rift

17. TWO GREAT EUROPEAN WATERWAYS

(Above) The Rhine Gorge, near Bingen, where every mile is touched with beauty. Tugs may be seen pulling heavily laden barges upstream. Compare the terraced hill-sides with the steep cliffs of the Iron Gate (*below*) where the Danube forces its way between the Carpathians and the Balkan Heights. Here the river is virtually impassable for shipping and a canal has been constructed along one side of the Gorge.

18. HUNGARY—THE DALMATIAN COAST

(Above) A shepherd and his flock on the Hungarian Plain. (Below) A view of the Boka Kotorska (Bocche di Cattaro), a complex opening on the Dalmatian coast of Yugoslavia, where three submerged longitudinal depressions are linked by transverse openings. Such longitudinal and transverse depressions are a feature of the Dalmatian coast. The town in the right foreground is Kotor (Cattaro) (see p. 238).

Valley and Gorge sections of the Rhine ; and (3) the North German Plain.

(1) **The Alpine Region**, which stretches from the foothills of the *Alps* across the *Alpine Foreland* to the Danube, is strewn with morainic material deposited by former glaciers, and with alluvium spread by post-glacial rivers. From the Alps descend swift tributaries of the Danube including the Lech, Isar, and Inn, whose waters have been harnessed for hydro-electric power. Much land has been cleared for cultivation, but forests are still a characteristic feature of the landscape, and saw-milling, paper-making, and peasant crafts, such as the carving of wooden toys, are important industries. The nature of the relief precludes the large-scale cultivation of cereals, but the soils with their varied mineral content support barley, wheat, hops, and sugar-beet, while in the well-watered meadows are grazed many dairy cattle, whose milk is made into butter and cheese. Settlement is confined to the valleys, where are found the few large towns and villages.

Munich (1,100,000), the capital of Bavaria, stands beside the Isar. Placed in the midst of a rich hop-growing and mixed farming district, it has for centuries been famous for its beer. Hence the construction of brewing and agricultural machinery are among its leading industries, as too is the building of locomotives. *Augsburg*, on the Lech, has cotton and light metal industries ; *Regensburg*, at the great northward bend of the Danube, imports grain from Hungary, and oil brought by river-tankers from Rumania.

(2) **The Central Uplands** are a region of great variety both in structure and relief. The streams flow in all directions, and, except for the Rhine valley, there is no really outstanding topographical feature.

In its course from Basle to Bonn the *Rhine* may be divided into two sections : (a) *The Rift Valley*, lying between the Black Forest Range and the Vosges and their northern prolongations, extends from Basle to Mainz. At Mainz the Rhine turns west, flowing along the foot of the Taunus Mountains, whose vineyards have for centuries been noted for their wine. (b) At Bingen the Rhine turns north and enters its *Gorge*, which is narrow as far as Coblenz, where the

Moselle enters the main stream, but broader from this town to Bonn. Here the hills recede and the Rhine enters its lowland course.

The Central Uplands are well forested, pines being the prevailing trees. Vines are widely grown on the lower slopes of such ranges as the Black Forest and the Vosges (France). Wheat, maize, and tobacco are important crops. There is considerable dairying in the valleys, while sheep are grazed on the uplands.

Among the chief German towns in the Rhine valley are *Mannheim* (290,000), a large river port at the confluence of the Neckar and the Rhine; with *Ludwigshaven*—noted for its chemical industries—on

FIG. 145. The Ruhr Industrial Area.

the opposite bank of the main stream; and the university town of Heidelberg, on the Neckar; *Mainz*, opposite the point where the Main joins the Rhine; and *Frankfurt*, 'the ford of the Franks', a short distance up the Main. Outside the valley and its margins, the principal town is *Nuremberg*, whose command of routes made it an important commercial city in the Middle Ages. It manufactures electrical apparatus and glass, for like so many other towns in Central and Southern Germany it specializes in the making of goods of high value in proportion to their bulk.

Germany's chief industrial areas are found on the coal-fields lying along the northern edge of the Central Uplands. The *Ruhr coal-field*, the greatest in Europe, produces 70 per cent. of Germany's hard coal, and 70 per cent. of her steel. The chief iron and steel towns are *Essen*, *Dusseldorf*, *Dortmund*, and the great river port of *Duisburg*, at the confluence of the Ruhr and the Rhine. They rely partly on German ores, but mainly on those from Lorraine and Sweden. *Solingen*, south of the coal-field, makes cutlery. Partly because of the huge local market, the Ruhr is the seat of textile manufactures, the leading centre being *Wuppertal*. *Krefeld*, west of the Rhine, makes rayon.

The small *Aachen* coal-field is an extension of the Franco-Belgian field. On the *Saxon* coal-field there are iron and steel plants at *Chemnitz* and *Zwickau*, both textile towns.

(3) **The North German Plain**, stretching from the Central Uplands to the North and Baltic Seas, is crossed by the Vistula (Poland), Oder, Elbe, Rhine, and other streams whose general direction is from

FIG. 146. Germany and its Margins: Minerals, and Distribution of Population.

south-east to north-west. Many of their tributaries, such as the Warta, a feeder of the Oder, flow in east-to-west valleys which have been utilized for the construction of canals linking the main streams. The Rhine is linked by the *Midland Canal* with the Elbe, and thence by other canals with Berlin, the Oder, and the Vistula. In Germany, as in France, rivers and canals are used for transport to a much greater extent than they are in the British Isles.

On the northern plain much marsh and moorland have been reclaimed for agriculture, and poor soils improved by the addition of fertilizers, such as potash, of which there are valuable deposits round Hanover, Stassfurt, and Halle. Not only is potash an extremely valuable fertilizer, but carbonate of potash is used in bleaching and dyeing, soap-making and calico-printing. Thus these potash deposits

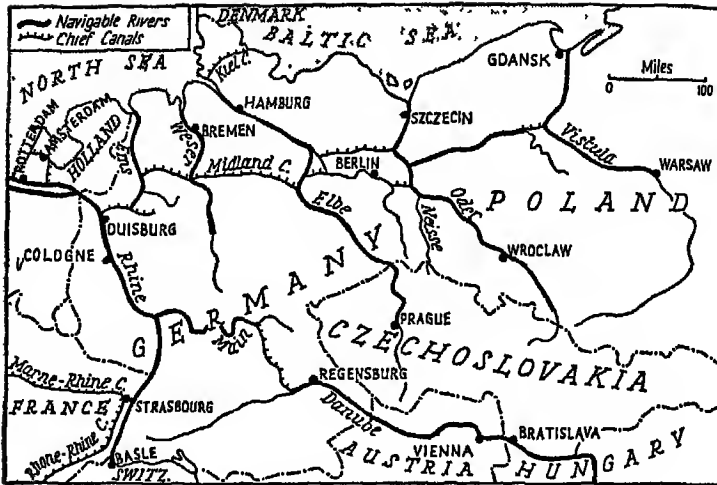

FIG. 147. Germany: Chief Inland Waterways.

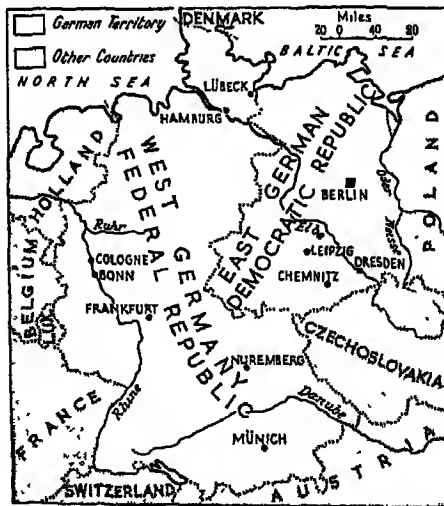

FIG. 148. Germany: Political Divisions.

have done much to assist German agriculture, and have helped to lay the foundations of the great chemical industries. As climate, configuration, and soils are similar over large areas, so too are crops. Rye and oats are the chief cereals, but wheat is grown on the better soils. Sugar-beet and potatoes are widely cultivated, the waste of

FIG. 149. Site of Berlin.

the former and much of the latter crop being used for feeding stock, notably pigs and cattle, which are widely reared, the bulk of the latter being found in the west. Sheep are widely grazed in the east, and horses are bred in the south of the Jutland Peninsula.

At the junction of the Central Uplands and the Northern Plain are a number of important towns. *Cologne* (800,000), the fourth largest town in Germany, stands at the head of ocean navigation on the Rhine at a point where land routes, coming down the Rhine valley, meet others running from west to east along the foot of the uplands. *Dresden* (500,000), the capital of Saxony, placed where the Elbe enters the plain, manufactures scientific apparatus; but the famous china is manufactured at Meissen, some dozen miles distant. *Leipzig* (610,000), west of Dresden, is a great publishing centre.

Berlin (3,400,000) was formerly the capital of the whole of Germany, and was the fourth largest city in the world, but in the last war much of it was laid in ruins. It is still a great manufacturing centre. Its position in the Northern Plain, midway

between the uplands and the Baltic, has helped to make it the focus of Germany's rail, road, water, and air routes.

The old Hanse town of *Lübeck*, and other Baltic ports, are usually blocked with ice in winter, but the harbours of Bremen and Hamburg are not frozen, though ice-breakers have to be used to keep the latter open. *Hamburg* (1,750,000), the chief port and second largest town in Germany, stands at the head of tidal navigation on the Elbe; *Bremen* lies 60 miles up the Weser. Most of the foreign trade of Western Germany passes through these ports, for as they face the North Sea the world is their market and the whole country is their hinterland. Both have a considerable Baltic trade through the *Kiel Canal*; and, owing to the excellent system of inland waterways, heavy and bulky goods can be forwarded cheaply by water to most parts of Germany. Besides being entrepôt ports, Hamburg and Bremen are industrial centres, as, by manufacturing imported raw materials at the port of entry, further transport costs are saved.

EXERCISES

1. Draw a sketch-map of Germany showing the *three* natural regions into which the country may be divided. In the case of *one* of the more important regions describe the principal occupations of the inhabitants and show how they are influenced by geographical conditions.

2. Describe the position of the chief German coal-fields particularly as regards neighbouring highlands and access to navigable waterways. In the case of the most important of the coal-fields, name the chief manufacturing industries and the principal towns concerned, and account so far as you can for the location of these industries in this vast industrial area.

3. (a) Draw a sketch-map of the Rhine. (i) Show the main stream, and *four* important tributaries; (ii) shade the high land; (iii) name the Rift Valley and the uplands bordering it; and the Gorge; (iv) show by suitable shading, and name, *one* important coal-field; (v) mark, and name, *six* large German, *one* French, *one* Swiss, and *one* Dutch town situated on the main stream or its tributaries; (vi) show by arrows the chief routes leading to the Rhine valley from France (two), Holland, Belgium, North-East Germany, Switzerland, and the Upper Danube. (b) Name *four* crops grown in the basin. (c) Give *three* reasons why the Rhine is important to Germany.

4. Among the industries of Hamburg are the manufacture of (i) iron and steel goods, (ii) chocolate, (iii) oil-cake, and (iv) the refining of sugar. Account for the location of these industries in this city.

5. Describe the part played by geographical conditions in the location and development of Munich, Cologne, Frankfurt-on-Main, and Dresden. Illustrate your answers by sketch-maps.

CHAPTER XV

THE DANUBE LANDS

CZECHOSLOVAKIA

THE Czechs, a progressive people, and the Slovaks, mainly of peasant stock, belong to the western branch of the Slav race. The Republic of Czechoslovakia was one of the new states carved out of

FIG. 150. Czechoslovakia.

the Austro-Hungarian Empire after the First World War. Its independence was, however, short-lived. In October 1938 Germany annexed the marginal districts of Bohemia, inhabited mainly by German-speaking peoples; Poland occupied part of the Teschen coal basin; and Hungary seized a portion of Slovakia and most of Ruthenia. In March 1939 Germany occupied the rest of the country, which remained under her rule until liberated after the Second World War. In 1945, Czechoslovakia ceded Ruthenia to Russia.

Czechoslovakia has a curiously elongated shape: it extends for some 400 miles from west to east, but nowhere does its breadth exceed 200 miles. Forested mountains separate the country from

Germany, Austria, and Poland, but the frontier with Hungary is ill-defined. Out of every 100 acres in Czechoslovakia 40 consist of arable land, 17 of pasture, and 33 of forests, yielding timber, wood-pulp, and tan-bark for leather industries. There are supplies of coal, iron, and water-power in Bohemia and Moravia, where manufacturing is highly developed. We may divide Czechoslovakia into three regions: (1) Bohemia, (2) Moravia, and (3) Slovakia.

Bohemia. The ancient crust-block of Bohemia, a diamond-shaped plateau almost encircled by wooded ranges, is an undulating region drained north by the Elbe and its tributaries, the chief being the Vltava (Moldau). Many cattle and pigs are raised and sheep are grazed on the uplands. Crops include wheat, barley, rye, potatoes, and flax; sugar-beet, widely grown, especially in the Elbe and Vltava valleys, and hops cultivated mainly around *Plzen* (Pilsen), famous for its breweries and iron and steel works. Timber, grain, dairy produce, and sugar-beet yield an export-surplus. *Coal* is mined on the slopes of the Erz Gebirge (Ore Mountains) round Teplice and Most; and *iron ore* is worked along a belt stretching from a point south of Prague towards Plzen. Local sands are used for glass-making, a traditional industry. Kaolin supplies raw material for porcelain works around *Karlovy Vary* (Karlsbad), a spa famed for its radioactive mineral springs. Their formation, and the presence of *uranium* ores (a source of atomic energy), worked in the locality, and in the Erz Gebirge (at Jachymov), are connected with the faulting and volcanic activity that once took place in this area.

Prague (Prahá), the capital, a city with 980,000 inhabitants, on the Vltava, stands on the main line from Vienna to Berlin, which leaves Czechoslovakia by the Elbe Gap between the Erz Gebirge and the Riesen Gebirge. It has large breweries, distilleries, sugar-refineries, and iron and steel works, and manufactures textiles and footwear.

Moravia. The valley of the Morava forms an easy route from the Danube northward to the valleys of the Oder and the Vistula by way of the Moravian Gate, the passage between the Sudetes and the Carpathians. Crops are similar to those of Bohemia, and dairying is important. *Ostrava* is the chief centre on the *Teschen coal-field*, which forms part of the Upper Silesian coal basin. *Brno*, the capital of Moravia, manufactures iron and steel goods and textiles. *Zlín* is noted for boot and shoe factories.

Slovakia stretches from the Danube to the crests of the Carpathians, where the snowy peaks of the High Tatra tower above the surrounding forests. Much of Slovakia consists of rolling wooded uplands and cleared valleys. The peasants grow rye and oats, graze sheep, and feed pigs on acorns and beech-mast in the forest glades. Strung along the valleys are straggling villages and sometimes a town. *Kosice* is a lumber and paper-making centre. *Bratislava*, a port on the Danube, exports timber and dairy produce; mills flour, and refines sugar and petroleum, brought by river-tanker from Rumania.

EXERCISES

1. Draw a sketch-map of Czechoslovakia. On your map insert and name Prague and four other important towns, including a river-port on the Danube. Show the chief railways leading from Prague.
2. Show how the environment affects the occupations of the people living in the Bohemian region.

AUSTRIA

Before the First World War, Austria was the leading partner in the Austro-Hungarian Empire. Present-day Austria is twice the size of Switzerland and has a population one and a half times as great. Though the Austrian Alps are lower than the Swiss they rise above the snow-line, and contain a number of glaciers the most famous being the Gros Glockner in the Austrian Tyrol. Austria is traversed by the Danube whose valley forms an important route. Its Alpine tributaries include the Inn and the Enns, which flow across the Alpine Foreland (see p. 225), and the Drave and its tributary the Mur, the former entering the main stream in Yugoslavia. Below *Linz*, a river-port and the capital of Upper Austria, the Danube flows through the Austrian Gate, a magnificent gorge leading to the Vienna Basin.

The lower slopes of the Alps are clad with forests, which furnish timber for saw-, pulp-, and paper-mills, furniture, and houses, which outside the large towns are constructed mainly of wood. In spring cattle are driven up from the valleys to the *alps*, or mountain pastures (compare Switzerland), where they remain until autumn. Upland crops include rye, oats, and potatoes. Wheat and sugar-beet are grown in the Vienna Basin, where, as in the Mur Valley, the sun-facing slopes are terraced for vineyards. Iron ore is worked at

Eisenerz, and lignite in the Mur valley, near *Graz*, an iron and steel centre. The *Salzkammergut*, the area round *Salzburg*, is noted for salt. *Innsbruck*, the capital of the Austrian Tyrol, is a popular tourist centre. It controls routes by the *Brenner Pass* to Italy, and the *Arlberg Pass* to Switzerland.

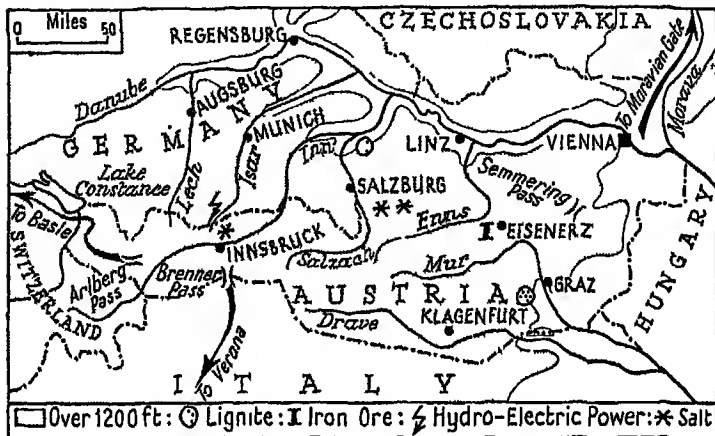

FIG. 151. Austria and Alpine Foreland.

Vienna (1,700,000), the capital, houses nearly a quarter of Austria's population. A great communications centre, it commands routes (a) by the Austrian Gate to Southern Germany; (b) by the Carpathian Gate to Hungary; (c) through the Moravian Gate to Southern Poland; (d) north-west via Prague and Dresden to Berlin; and (e) by the Semmering Pass (i) west to Innsbruck, and (ii) via Graz to Trieste and the Adriatic.

HUNGARY

The Hungarians are descended from Magyars and other pastoral tribes, who migrated from the Asiatic steppes, crossed the Carpathian passes, and settled on the Hungarian Plain, where the grasslands, termed *puszta*s, provided an environment not unlike that of their original home.

The dismemberment of the Austro-Hungarian Empire saw Hungary shorn of two-thirds of her territory, which was distributed amongst Rumania, Yugoslavia, and Czechoslovakia. Hungary, un-

like Austria, is mainly a land of fertile plains. There is little water-power. Lignite and iron ore are mined near *Miskolc* on the slopes of the Carpathians, and hard coal near *Pécs* in the south-west.

The Hungarian Plain is watered by the Danube, which in this portion of its course receives the Drave and other tributaries from the Austrian Alps, and the turbulent Tisa (Theiss) from the Carpathians.

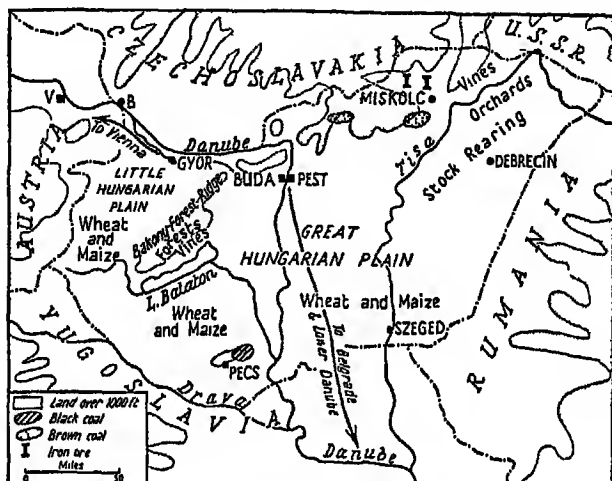

FIG. 152. Hungary.

On entering Hungary, the Danube crosses the *Little Hungarian Plain*, which stretches from the eastern frontier of Austria to the Bakony Forest Ridge, an outlier of the Alps, at whose eastern foot lies Lake Balaton. Passing through the Carpathian Gate (between the Bakony Forest Ridge and the Carpathians), the Danube enters the *Great Hungarian Plain*, or *Alföld* (= plain), flowing southward to cross the frontier into Yugoslavia.

The *Alföld* stretches from the Balkan Heights northward to the Carpathians, which from Bratislava (Czechoslovakia) sweep in a great semicircle, first north-east, then east, and finally south-west, approaching the Danube again at the gorge of the Iron Gate. In the course of centuries the steppe-like character of the *Alföld* has been modified: large tracts of swampy land have been drained and much grassland has been brought under the plough. To-day the *Alföld* is

one of the great granaries of Europe, for its rich alluvial soils, together with rainy springs and hot sunny summers, make it ideal for the cultivation of wheat and maize. Normally there is a surplus of wheat and flour for export. Much maize is fed to pigs and poultry, which are reared in large numbers. Sugar-beet and tobacco are also cultivated, as well as vines grown on the lower slopes of the Bakony Forest Ridge and those of the upper Tisa valley, which is famous for Tokay wine. The chief stock-rearing area lies around Debrecen, where cattle, sheep, and horses are grazed on the *puszta*s.

The population is not spread more or less evenly over the plain as in most agricultural regions, but is concentrated in enormous villages, or rather groups of villages, such groups not infrequently containing as many as 40,000 inhabitants. This unique arrangement is a survival from the days when the plains-folk, exposed to attack by their less prosperous neighbours in the surrounding mountain areas, gathered together for safety in huge settlements, which still show traces of their original lay-out as tent-encampments. *Debrecen* consists of a modern town closely encircled by primitive farming villages, the whole having a population of 122,000.

One of the few large towns in Hungary of the usual European type is *Budapest*, the capital. Standing at the entrance to the Carpathian Gate, it is a focus of routes approaching it from all parts of the plain. Buda stands on low hills overlooking the Danube: Pest, the commercial quarter, is spread along the low left bank of the river. Its industries include flour-milling, distilling, and tanning; it manufactures agricultural machinery and textiles, and refines petroleum. About one-sixth of Hungary's $9\frac{3}{4}$ million inhabitants live in Budapest and its suburbs.

EXERCISES

1. Give an account of the farming activities of the Hungarian Plain.
2. Describe a journey by steamer from Regensburg to Belgrade, mentioning the principal towns you would pass, and the different kinds of country you would see.
3. Compare the occupations of the North German Plain with those of the Hungarian Plain. Account as far as you can for the differences.

YUGOSLAVIA

After the First World War, Serbia and Montenegro, with Bosnia, Dalmatia, and other western provinces of Austria-Hungary, were

FIG. 153. Yugoslavia, Bulgaria, and Rumania.

united to form the kingdom of Yugoslavia. In 1945 it became a communist republic. Its area is 96,000 square miles, its population 18½ millions. Much of the country is mountainous: the highlands in the east are part of the Balkan Heights, those in the west form the Dinaric Alps. About a third of Yugoslavia is clad with forests of oak, beech, and pine yielding timber, wood for fuel, and acorns and beech-mast for feeding pigs, which, together with sheep, cattle, horses, and goats, are widely reared. Though primarily an agricultural country, Yugoslavia has considerable mineral resources, including coal, iron, lead, copper, and bauxite. About half its electricity comes from hydro-electric power plants.

There are three major Natural Regions: (1) the Dinaric Lands; (2) the Mountainous Central Region; and (3) the Danube Lowlands.

(1) **The Dinaric Region** includes Istria and the former Austrian provinces of Bosnia, Herzegovina, and Dalmatia. The limestone ridges of the Dinaric Alps, which run parallel to the Adriatic, are separated by deep longitudinal valleys. They form a region of the *Karst type*—a rock-strewn land with bare grey limestone hills between which lie plateaus and valleys, like that of the Narenta, cut deep into the soluble rock. *Shepherds pasture their flocks on the short, scanty herbage of uplands where rain never stays, but sinks through the porous ground to richly wooded and cultivated valleys far below.* In such a valley stands Sarajevo, on a tributary of the Bosna. East of this town the railway crosses the uplands of the Morava valley: west it descends to that of the Narenta, which it follows, past Mostar, to Dubrovnik on the deeply indented Dalmatian littoral, fringed with many islands, the peaks of a submerged mountain range.

The sinking of the Dalmatian coast allowed the sea to penetrate inland, through transverse openings, into the longitudinal valleys between the ranges. Thus it formed a series of complicated openings of which the best known is the Boka Kotorska, at the head of which stands Kotor (Cattaro). From this picturesque town a road winds up to *Titograd* (Cetinje), the capital of Montenegro. Farther north are the ports of *Dubrovnik* (Ragusa), *Split* (Spalato), and *Rijeka* (formerly Fiume), which is now the chief outlet on the Adriatic for Yugoslavia. Its climate sets Dalmatia apart from the rest of Yugoslavia, for it has the hot, dry, sunny summers and the mild rainy winters associated with the Mediterranean region. The lower seaward slopes of the mountains are clad with sub-tropical vegetation, while in the valleys olives, plums, vines, and mulberries are grown.

(2) **The Mountainous Central Region** corresponds roughly to the former kingdom of *Serbia*, which was spread round the Morava and Upper Vardar valleys. In these valleys considerable quantities of maize and wheat are grown, but the greater part of this region consists of forests and waste land. The Morava and Vardar valleys form an important route, followed by the railway from Belgrade via *Nis* (whence the Orient line to Sofia and Istanbul runs up the Nishava valley) to the Greek port of Salonika.

Belgrade (525,000), the capital of Yugoslavia, stands on high ground overlooking the confluence of the Danube and the Save, and a little to the west of the point where the Morava joins the main

stream. Somewhat similarly placed, in the transitional zone between the mountains and the Danube lowlands to the north, is *Zagreb* (290,000), on the Save, the chief manufacturing centre in the country, which mills flour, makes paper, and brews beer.

(3) **The Danube Lowlands**, forming the Yugoslav portion of the Alföld, rank with the Morava valley as the great grain-growing area in the country.

BULGARIA

The greater part of Bulgaria is mountainous, consisting of the forested Balkan Heights and the Rhodope Mountains. There are, however, two extensive lowland areas: (a) the plain stretching from the Balkan Heights to the Danube, and (b) the Maritsa valley in the south-east. Though rye, oats, potatoes, and other hardy crops are grown in the upland valleys, the Danube and Maritsa lowlands are the most important cultivated areas. Much wheat and maize are grown in both lowlands. Other crops are flax, sugar-beet, cotton, and sunflowers raised for their seeds, which yield oil. In the more sheltered Maritsa lowland tobacco (the chief export) and mulberries (for silkworms) are also cultivated. In the southward-facing valleys opening to the Maritsa are vineyards and plum orchards, and in some are rose gardens connected with the production of attar of roses.

Sofia (725,000), capital of this peasant state, lies where a number of routes converge on the Isker Basin, including those followed by the Orient Line to Plovdiv and Istanbul. *Plovdiv* (Philippopolis), the chief town in the Maritsa valley, is also linked by rail with *Ruse* (Ruschuk), Bulgaria's port on the Danube, and *Varna*, her Black Sea port. Study Fig. 153 and also the map in your atlas and note how the Orient Railways follow the valleys.

RUMANIA

As a result of the last war Rumania lost Bessarabia and certain other territory to Russia, and part of the Dobruja to Bulgaria. Comparable in area to Great Britain, Rumania has $17\frac{1}{2}$ million inhabitants. Nearly 80 per cent. of the working population are engaged in agriculture and forestry. We may divide Rumania into three main regions: (1) The Central Mountains; (2) the Danube Plains of Wallachia and Moldavia; and (3) Transylvania and the Banat.

(1) **The Central Mountains**, consisting of the Transylvanian Alps and the southern part of the Carpathians, form a barrier between the Danube lowlands and Transylvania. From them numerous streams, some harnessed for hydro-electric power, descend to the Danube. The mountains are thickly forested with beech and oak trees at lower elevations and pines and other conifers at greater heights. In spring timber is floated down the Pruth and Siret to the saw-mills at *Galatz*, a timber-exporting port near the confluence of the latter stream and the Danube.

(2) **The Plains.** The climate of the plains resembles that of the Hungarian Plain: the winters are so cold that the lower Danube is ice-bound, but the hot summers coupled with the spring rains favour the cultivation of wheat and maize, of which vast quantities are grown in Wallachia and on the fertile Black Earth Lands of Moldavia. Maize is grown principally for home consumption, but some wheat is exported. *Braila*, on the Danube, is the chief grain port. Other crops include flax, sugar-beet, and sunflowers. The steppes of the Dobruja plateau (loess-covered chalk), to the south of the Danube delta, are a pastoral area where many sheep are fed. The foothills of the Transylvanian Alps, of recent (Tertiary) formation, contain important deposits of petroleum (the leading export). From *Ploesti*, the chief centre, oil is piped to the Danube port of Giurgiu, and also to *Constanza*, on the Black Sea. From the latter port a railway, crossing the Danube at Cernovada, runs to *Bucharest* (1,250,000), the capital, whose industries—flour-milling, sugar-refining, brewing—like those of other towns on the plain, are based on agriculture.

(3) **Transylvania and the Banat.** The upland region of Transylvania is thickly forested. Cattle are bred on the upland pastures, pigs fed on the acorns and beech-mast, and agriculture is confined to the valleys where are situated the towns and villages. There is much undeveloped mineral wealth, but some iron and copper are mined. Much wheat and maize are grown in the *Banat*, which forms the eastern portion of the Hungarian Plain.

EXERCISE

1. Compare and contrast Yugoslavia and Hungary under the headings: Relief, Climate, and Products.

CHAPTER XVI

THE EUROPEAN MEDITERRANEAN LANDS

CONFIGURATION, CLIMATE, AND VEGETATION

THE formation of the Mediterranean was due to the subsidence of a considerable area between Europe, Africa, and Western Asia which allowed the ocean to penetrate far inland. This subsidence was preceded by other earth movements which resulted in the upfolding of those young mountains that, in part, encircle the Mediterranean. From Europe a series of peninsulas—the Balkan, Italian, and Iberian—project southward to the sea, where unsubmerged crust-blocks, like Corsica and Sardinia, and elevated areas, such as Sicily and Crete, remain as islands. The surrounding ranges tend to shut off the Mediterranean countries of Europe from their continental neighbours, though gaps, like the Gate of Carcassonne, and valleys, such as the Rhone, form important channels of communication.

Owing to the fact that there is little tide the rivers have built up deltas. The great ports of Marseilles and Barcelona are therefore not placed actually on rivers, but at the entrances to their valleys which furnish routes inland. Throughout the Mediterranean many ports are similarly placed at the mouths of valleys, but in most cases they are cut off by mountains from communication with their neighbours, while the restricted nature of their hinterlands handicaps their development. But they are linked by the sea. Yet despite the unifying effect of the Mediterranean Sea, which enabled the Romans and Arabs to extend their Empires throughout the Basin, the ultimate tendency has always been for the marginal lands to form distinct political units.

From the time of the Phoenicians up to the Middle Ages the Mediterranean was a great commercial highway, but with the discovery of the Americas trade routes shifted to the Atlantic, and it was not until the opening of the Suez Canal that the Mediterranean once more became an important artery of trade and one of vital importance to the Commonwealth.

The countries round the Mediterranean form a distinct natural region, unified by their *climate*, whose outstanding features are hot dry summers, mild rainy winters, abundant sunshine even in winter,

and a small annual range of temperature. The rainfall is greatest on coastal lands facing the prevailing winter westerlies, and taking the area as a whole it diminishes from west to east. But the varied topography of the region results in notable climatic differences. Thus the North Italian Plain, hemmed in on three sides by the Alps and Apennines and opening east, has a continental climate with considerable summer rain; while the Plain of Andalusia, facing the Atlantic, has a typical Mediterranean climate.

FIG. 154.

The *vegetation* is adapted to withstand the summer drought. Trees and shrubs are mainly evergreen and, like the olive, cork oak, laurel, myrtle, and arbutus, have small, thick, hairy, or oily leaves which prevent undue loss of moisture. Deciduous trees are limited to the better watered areas. There is an absence of summer pasturage suitable for cattle, though many sheep and goats are grazed on the rougher herbage of the uplands.

It has been aptly said that the Mediterranean man is a gardener rather than a farmer, for except in certain areas, like the North Italian Plain, the rugged relief prevents large-scale agriculture. Mixed farming is the rule. Of the cereals, wheat and barley are the chief. Neither requires irrigation, and barley, owing to its quicker growth, can be cultivated in areas too dry for wheat. Sown in autumn, the crops receive the benefit of the winter rains and are ready for harvesting in June. Little maize is grown on a large scale except in the North Italian Plain, where summer rains provide the necessary moisture, and on irrigated lands in South-East Spain. Rice, too, is

grown in both these areas. Typical Mediterranean crops are the vine and the olive. The long tap roots of the *vine* enable it to penetrate into the soil in search of moisture and also help it to resist frosts. The vine, which thrives on southward facing slopes, needs warm, sunny summers with but a light rainfall, and warm autumns (September 60° F.) to ripen the grapes. The *olive* requires more sunshine than the vine, but the trees can flourish in areas where the annual rainfall is as low as 8 inches, for their widespread surface roots enable them to collect the slightest moisture. But olives cannot stand cold, and even light frosts are fatal in spring. Favoured sites are the lower slopes of hills where the soils are warm and 'limy'. Spain, Italy, and Greece grow most olives, but they are also widely cultivated in Portugal and the lower Rhone valley. They are produced chiefly for their oil, which largely takes the place of butter in the diet of the Mediterranean people.

Citrus fruits, like *oranges* and *lemons*, require a slightly higher temperature than olives and a considerable amount of moisture. Thus they are chiefly found on irrigated lands in the Southern Mediterranean such as Andalusia and Sicily (lemons). Many warm temperate fruits are grown and vegetables are cultivated both as winter and summer crops, but in summer they require frequent watering.

EXERCISES

1. Draw a sketch-map of the Mediterranean. Insert and name Corsica, Sardinia, Crete, and Cyprus, and four important ports. Shade the higher lands surrounding the basin, and show by boldly drawn arrows three land and two water routes leading to the Western Basin, and two land and one water route leading to the Eastern Basin.

2. Among the principal Mediterranean crops are the olive and the vine. State fully the characteristics which enable these crops to thrive in this region. Name three important countries, or areas, for the production of each crop. State for what purposes grapes and olives are mainly used.

3. Discuss the importance of the Mediterranean sea route to the British Commonwealth.

THE IBERIAN PENINSULA—SPAIN AND PORTUGAL

Though the Pyrenees tend to isolate the Iberian Peninsula from the rest of Europe, railways run round both ends of the range and

FIG. 155. Iberian Peninsula: Natural Regions.

two lines cross it. The Peninsula is divided politically into Spain, with an area of 194,000 square miles, and a population of 28 millions; and Portugal, covering 34,000 square miles, with 8½ million inhabitants. The core of the Iberian Peninsula is an ancient crust-block, the Meseta, which has an average elevation of from 2,000 to 3,000 feet. It is bounded on the north by the Pyrenees and their continuation, the Cantabrians; and on the south by the Sierra Morena, rising abruptly from the Plain of Andalusia. The Meseta is crossed from west to east by *sierras*,¹ saw-toothed ridges which, rising a few thousand feet above the general level, hinder communications between north and south. From the Meseta the Ebro flows south-east to the Mediterranean, and the Douro, Tagus, Guadiana, and Guadalquivir to the Atlantic. In their plateau courses the rivers

¹ *sierra* = a saw.

speed through gorges so deep that their waters are useless either for navigation or irrigation; though some of the falls have been harnessed for electricity. The ancient (Archean) rocks are rich in minerals, notably silver, lead, quicksilver, and copper.

We may divide the Iberian Peninsula into four Natural Regions:

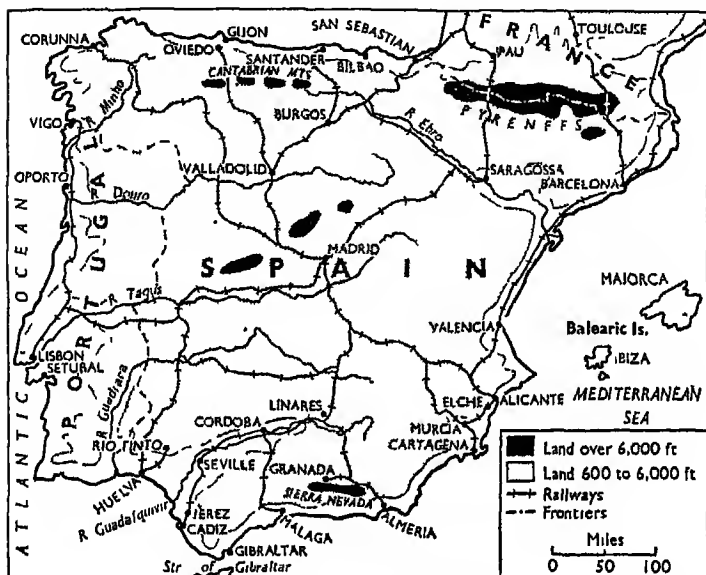

FIG. 156. Spain and Portugal.

(1) the Meseta, (2) the Mediterranean South and South-East, (3) the Maritime North and North-West, and (4) the Pyrenees.

SPAIN

(1) **The Meseta.** The high edge of the Meseta prevents rain-bearing winds from reaching the interior, which has a continental climate, with hot summers, cold winters, and a scanty rainfall. The plateau is almost treeless and in some districts is little better than a desert. The cold winters prevent the cultivation of Mediterranean products like the olives. Wheat is grown on the lower slopes of the Cantabrians and on irrigated lands round Valladolid. Many sheep and

goats graze on the poor pastures. It was from Spain that merino sheep were exported to Australia to form the foundation of many flocks there. Local wool is made into cloth at Burgos, an ancient city and focal point in the Douro basin. In the south, copper, mined at *Rio Tinto*, is exported from Huelva; Almaden has valuable quick-silver mines; silver and lead are obtained from Linares. *Madrid* (1,850,000) was chosen to be the capital of Spain because of its central position, which later made it a focus of railways. A study of the railway map shows that the rugged relief makes transport difficult. Thus, from whichever way they approach the Meseta from the coast, the railways have to zig-zag up its steep sides, and pass through many tunnels to reach the capital.

(2) **The South and South-East** have a Mediterranean climate, but the winter rainfall is small, especially along the east coast, lying in the lee of the rain-bringing westerlies. In *Andalusia*, which opens to the Atlantic, it is somewhat greater. This rich lowland, forming a wedge between the Sierra Morena and the Sierra Nevada, is drained by the Guadalquivir. Oranges, of the bitter type used for marmalade, are widely grown, being exported from *Seville*, a river port some 75 miles up the Guadalquivir. Vines are extensively cultivated. The district round Jerez is noted for its sherry, which is shipped from *Cadiz*. Andalusia is the chief olive-oil producing region in Spain. The trees are grown on the terraced slopes of the Sierra Morena and the Sierra Nevada, where groves are found as high as 3,000 feet round *Granada*, the last stronghold of the Moors. From the south-west of Andalusia forests of evergreen cork-oak extend across the frontier into Southern Portugal.

Along the *South-East Coastlands* maize, cotton, sugar-cane, rice, and even bananas are grown on irrigated lowlands, while vines and olives flourish on the lower slopes of the hills. So hot are the summers that dates ripen round Elche, on the railway from Alicante inland to Murcia. Raisins are exported from *Malaga*, other fruit-exporting ports being Cartagena and *Valencia* (535,000).

Barcelona (1,400,000), the capital of Catalonia, is the chief port and commercial centre and largest town in Spain. Power for its cotton factories is generated from the waters of the Segre (a tributary of the Ebro) and from other streams descending from the Pyrenees. From Barcelona a line crosses to the Ebro valley, which it follows

to Saragossa, the chief town of Aragon, and thence to San Sebastian, on the Bay of Biscay. Barcelona is the port for the *Balearic Islands*, of which the largest is Majorca, whose capital is Palma.

(3) **North and North-West Spain.** This maritime and well watered region, lying between the Cantabrians and the Bay of Biscay, presents a striking contrast to the rest of Spain. Beech, oak, chestnut, and pine woods clothe the rain-drenched slopes of the mountains; on the lowlands wheat, roots, and fruits are grown; and cattle graze in the lush meadows.

Northern Spain is rich in *iron ore*. As the mines lie close to the coast the ore can be exported cheaply by water from *Bilbao*, *Santander*, and *Gijon*. *Coal*, mined round *Oviedo*, is used for local iron industries and in the chemical and glass works of Bilbao. There are sardine fisheries, for which *Corunna* and *Vigo*, on the west coast, are the leading centres.

(4) **The Pyrenees** have already been described (see p. 189).

PORTUGAL

On the west the Meseta slopes to a wide plain across which the Minho, Douro, and Tagus flow into the Atlantic. South of the Minho this western portion of the Iberian Peninsula forms Portugal. We may divide the country into two natural regions each of which forms part of the corresponding climatic and adjacent region in Spain. (1) Northern Portugal has a maritime climate; while (2) Southern Portugal, with its Mediterranean climate and products, resembles Southern Spain.

(1) In **Northern Portugal** forests of beech, walnut, and pine clothe the windward slopes of the mountains, while vines are cultivated in the less exposed valleys. Some 60 miles up the Douro valley are the famous vineyards whose grapes are made into *port*, exported from *Oporto* (285,000), a few miles from the open sea.

(2) In **Southern Portugal** olives, oranges, and vines are grown, but much wealth is derived from the forests of evergreen oak, from the bark of whose trees cork, the chief export of the country, is obtained. *Lisbon*, the port-capital, is a junction for air-traffic from all parts of

the world. It is the only manufacturing city in the country, making textiles, 'finishing' cork, and tinning sardines. But the chief centre of the sardine industry, which after cork and wine provides the third chief export of Portugal, is Setubal, some 26 miles south of Lisbon.

Portugal still retains considerable overseas possessions. In the Atlantic she owns the *Azores* and the *Madeira Islands*, both of which are regarded as an integral part of the republic, as well as the *Cape Verde Islands*. To these must be added her extensive possessions on the mainland of Africa, and her territories in China and the East Indies. These lands not only supply her with raw materials such as coffee, sugar, and cotton, but form a market for her textile and other manufactured goods.

GIBRALTAR

The Rock of Gibraltar, a British Crown Colony, has an area of nearly 2 square miles. It owes its strategic importance to its position at the eastern end of the Strait of Gibraltar, leading from the Atlantic to the Mediterranean Sea.

EXERCISES

1. Draw a sketch-map of the Iberian Peninsula and on it indicate the chief natural regions. Describe the climate, characteristic products, and occupations of *one* of the more important regions.
2. What geographical factors have determined the site and contributed to the growth of each of the following: Madrid, Barcelona, Valencia, and Lisbon? Illustrate your answer by sketch-maps.
3. Spain possesses valuable minerals. Name the chief minerals, stating the areas from which they are obtained, and through what ports they are exported. Give a map.

ITALY

Italy has an area of 131,000 square miles, and a population of 50 millions. She is advantageously placed, for she commands seaways leading from the Western to the Eastern Basin of the Mediterranean, and land routes, by way of the Alpine passes, to Central and Western Europe. The parallel ranges of the Apennines run for 800 miles through the entire length of the Italian Peninsula. Diverging from the Alps at the Altare Pass, north of Savona, they form the southern margin of the North Italian Plain, thus shutting it off from Peninsular Italy. Little more than half the land is suitable for

19. SCENES IN ITALY

(Above) An aerial view of Rome showing the Colosseum in the left background. (Below) Another phase of the Italian scene—Vesuvius, the volcanic cone dominating the Bay of Naples, in eruption, seen from the edge of the crater. Vesuvius is known as a 'mixed' volcano, for besides lava it emits ashes, dust, scorrae, &c. In the eruption of A.D. 79, Pompeii was buried beneath clouds of ash, and Herculaneum under a sea of boiling mud. The last great eruption occurred in 1929.

20. HISTORY IN STONES

(Above) Though no longer important for defence these castles along the Bosphorus remind us of the strategic importance of this strait, one of the links between the Mediterranean and the Black Sea (Below) The Alhambra at Granada the last stronghold of the Moors and

cultivation, yet 70 per cent. of the people are engaged in agriculture.

The three main regions are : (1) the North Italian Plain and Alpine Italy, (2) Peninsular Italy, and (3) Insular Italy.

(1) **The North Italian Plain and Alpine Italy.** The North Italian Plain, lying between the Alps and the Apennines, is a depression, once an arm of the Adriatic, which has been filled up by waste brought down from the Alps by the Po and its tributaries. The Alpine streams, fed by heavy rains and swollen in spring and summer by melting snows, unlike those descending from the Apennines, have a constant flow throughout the year and thus supply water both for irrigation and hydro-electric power. Because of the great amount of sediment it carries, the Po is steadily raising its bed and in its lower course actually flows at a higher level than the surrounding land. This facilitates irrigation, but as it makes the river liable to flooding few towns are built on its banks.

Of the streams descending from the Alps the Ticino drains Lake Maggiore, the Adda Lake Como, and the Mincio Lake Garda—long, narrow, mountain lakes, formed by the damming up of the lower ends of the valleys by morainic material. These southward-facing valleys of *Alpine Italy*, owing to their aspect and sheltered position, have a much milder climate than the Po lowlands. Thus the vine, the olive, and in specially favoured districts, as round Lake Garda, the orange can be cultivated. Such valleys are usually well wooded with sweet chestnuts on the lower slopes and pines at higher elevations.

On the other hand, the *Northern Plain* itself, shut off from the influence of the Mediterranean by the Apennines, has a continental climate. The summers are as hot as those of Southern Italy, but the winters are much colder. Rain falls throughout the year, being heaviest in early summer and autumn. In the south are stretches of meadow land on which are reared many cattle whose milk is made into cheese, such as gorgonzola. Wheat and maize are grown, and the sun-baked villages are surrounded by vineyards and rows of clipped mulberry trees, whose leaves are used to feed silkworms which provide silk for factories at Milan and Como. So hot are the summers that rice can be grown on irrigated lands, but the winters are too cold for olives, which cannot stand prolonged frosts.

Most of the chief towns lie either at the entrances to valleys which

lead up to passes across the Alps, or at the base of the Apennines. *Turin* (720,000), standing on the upper Po, where the river is not yet too great in volume to be controlled in time of flood, commands

FIG. 157. Sites of Milan, Turin, and Genoa.

the Mont Cenis route leading to the Rhone valley. It makes textiles and motor-cars. *Milan* (1,300,000), the chief industrial city in Italy, is placed where routes by the St. Gotthard and Simplon Passes reach the Plain. It has cotton, silk, rayon, and tyre factories, and railway works. The factories obtain their electricity from hydro-power stations. Owing to the development of her water-power resources, notably in the Alpine region, Italy's hydro-electric output is as great as that of any country in Europe.

Verona, on the Adige, commands the Brenner route to Austria. *Venice*, built on a number of small islands in the Adriatic and protected on her landward side by marshes, was one of the leading maritime republics of the Middle Ages. Her importance declined with the discovery of America and the shifting of trade routes to the Atlantic, and the opening of the Suez Canal did little to restore her prosperity. Today she is mainly known as a pleasure resort; and as a port ranks behind *Trieste*, at the head of the Adriatic, with steel-works, shipyards, and oil-refineries.

Situated at the foot of the Apennines and built on firm ground above the marshes of the plain are a number of ancient cities. Among them are *Alessandria*, a railway junction, whence a low pass over the Apennines leads to *Genoa*; *Parma*, *Modena*, and *Bologna*, the last commanding a pass across the mountains to *Florence*.

(2) **Peninsular Italy.** The Apennines form the backbone of Peninsular Italy. Around the Gulf of *Genoa* they rise steeply from the sea, but farther south they recede, leaving the plain of *Tuscany*, drained by the *Arno*; *Latium*, crossed by the *Tiber*; and the *Cam-*

pania round Naples. From Ancona southward the Apennines run close to the Adriatic and, except in the lowland of Apulia, the coastal plain is narrow and sometimes absent. Apart from Brindisi the east coast has no good harbours while few easy routes lead inland. The west coast, with a number of good harbours and valleys leading to the interior, has throughout historic times been more important.

The climate and products of Peninsular Italy are typical of the Mediterranean Lands. There is little pasture suited for cattle, but many sheep and goats are reared, feeding in summer on the upland herbage and returning in winter to the lowlands. Wheat, which occupies one-third of the arable land in Italy, is widely cultivated round Naples; on the plain of Apulia, which produces a particularly hard kind used for making macaroni; and on the recently reclaimed lands of the Pontine marshes, south of Rome. Vines for wine and olives for oil are much grown; the hill-sides of the Arno valley being famed for the latter crop. Artificial watering is necessary for vegetables, which in some districts are planted between the trees in orchards, vineyards, and olive groves, and in others are grown in market gardens.

Genoa (670,000), commanding several easy passes over the Apennines into Piedmont and Lombardy, is the chief outlet for the Northern Plain. From Genoa the electrified railway to Southern Italy runs along the foot of the mountains, through many tunnels, past Carrara, noted for its marble, to Pisa, at the mouth of the Arno, which, owing to the silting up of the river, has yielded its position as a port to Leghorn, to the south. From Pisa the southward route continues along the coast to Rome; eastward the railway traverses up the valley of the Arno to *Florence*, a bridge town built where the river leaves the mountains and enters the plain. From Florence the railway to Rome continues up the valley of the Arno and then down that of the Tiber. *Rome* (1,700,000), the capital and largest town in Italy, was built on low but steep hills on the left bank of the Tiber, to which point the river was navigable for small boats, and where an island in the stream made it possible for it to be bridged. Its importance is, however, mainly due to historical and religious causes. Within Rome lies the *Vatican City*, an independent state ruled by the Pope. From Rome the railway continues to *Naples* (1,000,000), the third largest city in Italy, picturesquely placed on a magnificent bay dominated by the active volcano of Vesuvius. An important

port, it manufactures olive oil, soap, flour, macaroni, and textiles. Still following the coast the line runs past many villages, shut in between the mountains and the sea, whose people are engaged in the sardine, tunny, and anchovy fisheries of the Tyrrhenian Sea. Reggio stands on the narrow Strait of Messina, opposite the town of Messina in Sicily. The strait was formed by an exceptionally deep-seated fracture of the earth's crust, which accounts for the severe earthquakes in this area, such as that which in 1908 entirely destroyed Messina and Reggio; both were subsequently rebuilt.

(3) **Insular Italy.** Of the Italian islands in the western basin of the Mediterranean by far the most important is *Sicily*, dominated by Etna, the volcano which rises to 10,800 feet and which is nearly 100 miles in circuit at its base. Somewhat larger than Wales, Sicily is one of the most densely peopled portions of Italy. Its crops resemble those of the Peninsula. Sulphur is shipped from *Catania*, but a greater amount is obtained from mines near Girgenti. *Palermo* (500,000), the capital, exports the olive oil, oranges, and lemons for which the island is noted. Owing to its position athwart the sea-way leading from the Western to the Eastern basin of the Mediterranean, Sicily has been from early times of great strategical importance. The *Lipari Islands*, with the volcanic cone of Stromboli, lie to the north-west of Sicily.

Sardinia, a mountainous and thinly peopled island, about the same size as Sicily, is separated from the French island of Corsica by the Strait of Bonifacio. Its capital is the port Cagliari, in the south. Much of Sardinia is covered with poor forest and evergreen scrub (*maquis*). Its chief value to Italy—a country poor in minerals—lies in its lead and zinc mines. There are hydro-electric power stations, e.g., on the Tirso River. *Elba*, an island off the coast of Tuscany, produces iron ore.

Foreign Trade. Italy's *exports* include citrus and other fruits, textiles, motor vehicles, and machinery. Among the *imports* are cotton, iron and steel, crude oil, and coal. The value of the imports exceeds that of the exports, and the adverse balance is made up by profits from shipping, money spent by tourists, and funds from Italians abroad.

FIG. 158. Routes and Towns of Italy.

Malta. Some 60 miles south of Sicily lie the islands of Malta, (95 square miles) and Gozo (26 square miles), which together have a population of 300,000. Farming is the chief occupation. Valetta, the capital stands on a fine harbour. Malta has a commanding situation, between Sicily and Tripoli, and midway on the route from Gibraltar to the Suez Canal. The island was formerly the chief British naval and air base in the Mediterranean.

ALBANIA

This small highland state lies on the east of the Adriatic. Most of the country is a rugged region forming the southern portion of the Dinaric Alps, which here recede somewhat from the sea. Along the Adriatic littoral Mediterranean products are grown. The highlands are mainly pastoral. Hardy crops are cultivated round the isolated villages, where each family grows enough for its own needs and rears a few animals for meat, milk, and wool. Durres (Durazzo) is the only modern port. *Tirana* is the capital.

EXERCISES

1. Select two important inland towns and two of the chief sea-ports in Italy. Illustrating your answer by sketch-maps, describe the situation of each, and discuss the geographical causes that have contributed to their growth.
2. Draw a sketch-map of Italy and on it indicate the major natural regions. Contrast the two major regions with respect to climate, and the resulting types of farming.
3. Describe a railway journey from Naples to Venice, so as to bring out clearly the contrasting types of country that you would see. Use your atlas.

GREECE

Of the three mountainous peninsulas stretching southward into the Mediterranean, the most easterly one, together with *Crete* and numerous islands in the Aegean and Ionian Seas, forms Greece. This state, about the size of England, has, like that country, had an influence on the history of the world altogether out of proportion to its size.

The sinking of the earth's crust in this part of the Eastern Mediterranean allowed the sea to cover the less elevated portions, leaving the peaks as islands and converting the lower ends of the valleys into bays. In such valleys, often separated by barren uplands from their neighbours but linked by sea, rose up the Greek City States, whose colonies spread throughout the Mediterranean, and whose ideals played so great a part in shaping Western Civilization.

Four-fifths of Greece is mountainous. As the rivers usually flow in deep gorges they are of little use for irrigation. In most parts the climate is dry, though the western coasts and the Ionian Islands,

which in winter face the prevailing westerly winds, receive a considerable rainfall. (Compare Corfu, 50 inches a year, with Athens, only 15 inches.) Iron is the chief mineral. Greece is primarily an agricultural country, but of the total area only one-fifth is suitable for cultivation. Wheat is the chief cereal, while lemons, oranges, figs, and tobacco are grown and olives and vines cultivated on terraced

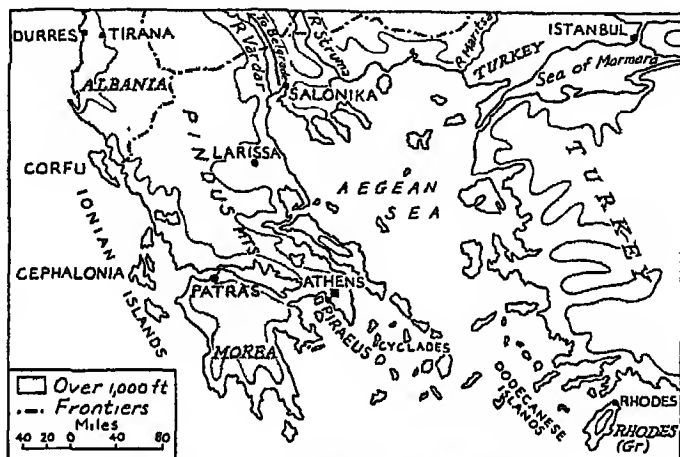

FIG. 159. Greece and the Aegean Sea.

hill-sides. The district along the northern shores of the Gulf of Corinth, the western and southern coasts of the Morea Peninsula, and the Ionian Islands of Zante and Cephalonia are famous for their currants, which are exported from Patras. *Athens* (1,200,000), the capital, standing at the base of the historic Acropolis, lies some five miles from Piraeus, its port.

Mulberries, cotton, and tobacco are grown on the plain of Eastern Greece, which stretches from the slopes of the Rhodope Mountains to the Aegean. *Salonica* (310,000), the chief port of Greece, commands the Vardar-Morava route, followed by the railway to Belgrade, on the Danube. Its exports include tobacco.

The mountainous island of Crete is the largest of the Greek islands. They also include the Dodecanese group, south-west of Asia Minor, of which the chief is Rhodes.

EUROPEAN TURKEY

All that remains of the once great Turkish Empire in Europe is the region stretching from the Sea of Marmara and the Black Sea westward to Edirne (Adrianople), well placed on a defensive site at the confluence of the Maritsa and one of its tributaries. But though the seat of the government of the Turkish Republic has been trans-

FIG. 160. The Site of Istanbul (Constantinople).

ferred to Ankara, *Istanbul* (Constantinople) still remains by far the largest city in Turkey. Wonderfully situated on the Golden Horn, an arm of the Bosphorus, and commanding the route across that strait from Europe to Asia Minor, as well as the seaway through it leading from the Aegean and Sea of Marmara to the Black Sea, it has from early times been a place of great strategic and commercial importance.

EXERCISES

1. Show how the geographical conditions have influenced occupations in Greece.
2. Describe, with the aid of sketch-maps, the importance of the position of (a) Saloniki and (b) Istanbul. Can you suggest any reasons why the Turks transferred their capital to Ankara, in Asiatic Turkey?
3. Compare the western and eastern coasts of the Adriatic, and state in what respects they are similar and in what respects they differ from each other. Discuss each coast in its relation to human settlement.

PART III

ASIA

CHAPTER XVII

GENERAL SURVEY OF ASIA

POSITION AND SIZE

ASIA, the largest continent, occupies one-third of the land surface of the globe. It extends from 26° E. to 170° E. and from within 12° of the North Pole to within 1° of the Equator, or including the Malay Archipelago to 10° S. Thus the mainland lies wholly within the Northern Hemisphere. From Europe, Asia stretches eastward to the Pacific; from the Arctic south to the Indian Ocean, into which project the peninsulas of Arabia, India,¹ and Indo-China. With the exception of New Guinea and the Aru Islands, which belong to Australia, the islands of the East Indies are regarded as part of Asia. This division between Asia and Australia is based on a line of fold mountains which can be traced from the Malay Peninsula through Sumatra and Java to the Philippines. Formerly Wallace's line, depending on differences of flora and fauna, was regarded as the boundary between the two continents.

Though Asia is margined on three sides by oceans it has, in proportion to its size, few indentations. Over one-third of the continent, or an area one and a half times the size of Europe, is more than 600 miles from the sea.

STRUCTURE, RELIEF, AND DRAINAGE

We can divide Asia into six major physical divisions: (1) the Central Fold Mountains and Intermont Plateaux; (2) the Eastern Volcanic Islands; (3) the North-East Highlands; (4) the Southern Tablelands; (5) the Alluvial Plains of South-East Asia; and (6) the Northern Plain.

(1) **The Central Fold Mountains and Plateaux**, part of the Mid-World Mountain System which stretches from Europe to the Pacific, form a barrier to climatic influences and communications between the south-east of Asia and the north-west. The arrangement

¹ In this chapter *India* is regarded as a geographical unit.

of the system is best grasped if we remember that (a) the ranges radiate from two great mountain knots—the Pamir Plateau and the Armenian Knot, and (b) that they enclose huge and lofty plateaux,

FIG. 161. Asia: Relief and Drainage.

which have a scanty rainfall and form regions of inland drainage.

Starting in the west, note, on Fig. 161 and in your atlas, the position of the ranges and plateaux.

(a) The Armenian Knot is separated from the Caucasus Mountains by the Kur rift valley.

(b) From the Armenian Knot the Pontic Mountains run west, and the Anti-Taurus and Taurus south-west to enclose the Plateau of Asia Minor.

(c) The *Plateau of Iran* is shut in by fold mountains. From the *Armenian Knot* one line runs from the *Elburz Mountains* through the *Hindu Kush* to the *Pamirs*. Another line forms a southerly loop round Iran. Trace it from the *Armenian Knot* through the *Kurdistan Highlands* and thence along the southern margin of the *Plateau* and finally north-east through the *Sulaiman Mountains* to the *Pamirs*.

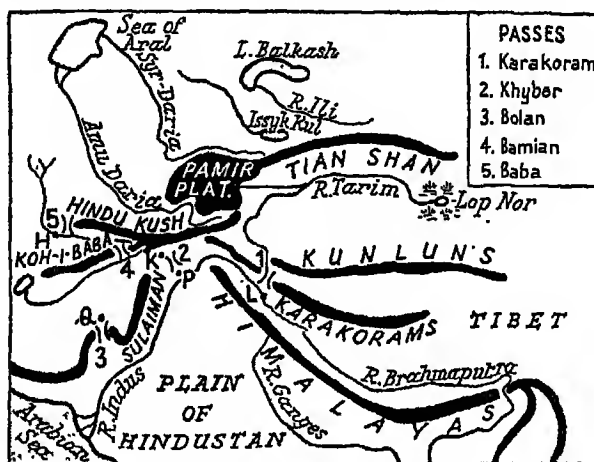

FIG. 162. Asia: The Central Mountains.

(d) From the *Pamirs* the *Tien Shan* run north-east and the *Kunlun* east to enclose the *Tarim Basin*.

(e) The *Plateau of Tibet*, standing at a height of from 14,000 to 17,000 feet above sea-level, is margined by the *Kunlun Mountains* and the *Himalayas*.

(f) From the eastern end of the *Himalayas* great fold ranges (deflected by the *Plateau of Yunnan*) run south through *Burma* as the *Arakan Yoma* and *Pegu Yoma*. Thence they may be traced (i) through the *Andaman* and *Nicobar Islands*, *Sumatra*, and *Java*; (ii) by the *Malay Range*, the backbone of the *Malay Peninsula*; and (iii) through the *Annam Range* running between the *Mekong valley* and the *South China Sea*.

(2) **The Eastern Volcanic Islands**, stretching from the *Malay Archipelago* through the *Philippines*, *Formosa*, and *Japan* to the

Kamchatka Peninsula, are the unsubmerged portions of a fold mountain range. The higher portions form islands separated from the mainland by a series of seas.

(3) **The North-East Highlands**, running from the Central Fold Mountains and Plateaux to the extreme north-east of Asia, are very ancient and much denuded uplands. The *Altai* and *Sayan Mountains* are separated by Lake Baikal from the *Yablonoi Mountains* in which the Amur (2,500 miles) rises. Notice how the *Mongolian Plateau* is shut in by spurs of the *Altai* and *Sayan Mountains* on the north, by the *Nan Shan Mountains* on the south, and the *Khing'an Mountains* and *Shansi Highlands* on the east.

(4) **The Southern Tablelands** of Arabia and Peninsular India are crust-blocks. Like most structural areas of this type they are difficult of access.

(5) **The Alluvial Plains** of South-East Asia include the Mesopotamian Lowland built up of sediment brought down by the Tigris (1,100 miles) and the Euphrates (1,700 miles); and the Indo-Gangetic Plain, or the Plain of Hindustan, composed of alluvium deposited by the Indus (1,800 miles), the Ganges (1,500 miles), the Brahmaputra (1,800 miles), and their tributaries. Other alluvial plains include the lower basins of the Irrawaddy, the Salween, the Mcnam, the Mekong, the Yangtze-kiang (3,400 miles), and the Hwang-ho (2,500 miles).

(6) **The Northern Lowland**, an extension of the Great European Plain, is broadest in the west. It may be divided into two portions: (i) the *Siberian Plain*, drained to the Arctic by the Lena (2,500 miles), the Yenisei (3,200 miles), and the Ob (2,800 miles); and (ii) *Turan*, forming the south-west portion of the lowland, which is drained partly to the Caspian, but mainly to the Sea of Aral, into which flow the Amu Daria (1,300 miles) and the Syr Daria (1,100 miles). Turan forms part of the huge inland drainage area of Central Asia.

CLIMATE

The enormous size, compactness, range of latitude, and relief of Asia combine to produce great climatic contrasts. As most of the continent lies far from the sea a considerable area has a continental climate, with extremes of heat and cold. The great central mountain system acts as a barrier both to cold influences from the north, and

to warm influences and rain-bearing winds from the south ; while the elevation of this and other areas further accentuates climate differences. By far the most striking feature about the climate of Asia is the monsoons. The summer monsoon winds, flowing in from the Indian and Pacific Oceans, which cause heavy rains to fall over South-East Asia during the hottest and most productive part of the year, are the main reason for the abounding fertility and dense population of the great alluvial plains of this part of Asia.

FIG. 163. Asia : Winter (January) Temperature.

FIG. 164. Asia : Summer (July) Temperature.

Temperature. Broadly speaking, *January* temperatures decrease from south to north (Fig. 163). The general direction of the January isotherms is from east to west, though their northward bend along both the Pacific and Mediterranean coasts shows the moderating effect of the sea in these regions. Winter temperatures far below freezing-point are found over the whole of Central and Northern Asia. Nearly the whole of Siberia has a January temperature below zero. Verkhoyansk, just within the Arctic circle, the coldest place in the world, has a January temperature of -58.9° F.

In *July* temperatures also show a general decrease from south to north, though the cooling influence of the Pacific on the coastal areas is shown by the southern bend of the isotherms in that region (Fig. 164). For a similar reason Malaya and the East Indies are somewhat cooler than Arabia, Iran, and Northern India, which lie farther

north. In July Central Siberia is slightly warmer than Southern England, but the Arctic coast is cool.

Winds and Rainfall. (1) Though the Monsoon Climate is most marked in India, the whole of south-east Asia belongs to this climatic régime. The marked pressure changes from winter to summer over Central Asia cause remarkable seasonal changes of

FIG. 165. Asia: Rainfall and winds, November to April.

FIG. 166. Asia: Rainfall and winds, May to October.

winds. In *winter*, owing to the intense cold, a region of high pressure, with outflowing winds, is found over Central Asia. The centre of this system is over the Gobi Desert, but it extends far to the north. The air over the ocean is relatively warm, for it has been absorbing heat during the summer, and so cold heavy air flows from the high pressure belt towards the regions of lower pressure over the Pacific.

But as the plains of Northern India are cut off by the enormous barrier of the Himalayas from Central Asia, the high pressure area in the latter region is not responsible for the winter monsoons of India. In winter the Indus basin is an area of high pressure from which winds blow gently outwards down the river valleys towards the ocean. These winds are not exceptionally cold, and even in the north of the Indian sub-continent the winters are less severe than in Central and Northern China. The general direction of the winter

monsoon winds is from the north-north-west in China, and the north-north-east in India. As they blow from land to sea they are dry winds, except in areas like the east coast of Annam, South-East India, and Ceylon, where they reach the land after crossing an expanse of ocean.

In *summer* conditions are reversed. The land heats much more rapidly than the sea and becomes a region of *low pressure* with

FIG. 167. Rainfall and Temperature at Calcutta, Penang, and Peking.

inflowing winds. The centre of this low pressure system lies just north of the Tropic of Cancer over Baluchistan and Sind. From this area the low pressure extends westward to Arabia, and north-east over the continent. In India, the moisture-laden winds from the Indian Ocean blow from the south-west. In China, south-east winds blow from the Pacific. These inflowing winds bring to South-East Asia copious rains, which are especially heavy on the windward slopes of the mountains (Figs. 165, 166).

The *essential feature of the monsoon climate* which is most marked in Asia is the *seasonal change of wind*. Generally speaking, winters are dry and summers wet. It should, however, be clearly understood that *temperature conditions do not, of necessity, form part of the definition*. For example, the following towns all have a monsoon climate with hot rainy summers and dry winters; but the January temperature at Calcutta is 65° F., at Penang 80° F., and at Peking (Peiping) 24° F. (Fig. 167).

We must, therefore, distinguish between :

- (a) The *tropical monsoon climate* of India, Indo-China, and Southern China.
- (b) The *equatorial monsoon climate* of the Malay Peninsula and the East Indies, where the typical monsoon régime is modified both by latitude and maritime situation. In this region temperatures are uniformly high. Rain falls at all seasons, but in most areas the rainiest months are from May to October, while December and January are relatively dry. (Compare with India.)
- (c) The *temperate monsoon climate* of North-East Asia, which includes Central and Northern China, Manchuria, and Central and Southern Japan.

(2) North-west of the Monsoon Region a *desert and arid belt* stretches from Arabia, through Iran and Turkestan, into Mongolia. The annual rainfall is under 10 inches and irrigation is essential for cultivation. The lack of rain is due to several causes. Arabia and the southern part of the Plateau of Iran receive little rain because they lie in the trade wind desert belt. The Plateau of Mongolia is dry partly because (1) it lies so far from the sea, and (2) marginal mountains increase the aridity of the climate.

(3) On the north-west the desert and arid belt merges into the *Mediterranean Lands* (Asia Minor, Syria, Lebanon and Israel), with hot dry summers and mild showery winters. The influence of the Mediterranean extends into Mesopotamia and the Plateau of Iran, though summers grow hotter, winters colder, and winter rainfall slighter with increasing distance from this sea.

(4) The rainfall in the *Cool Temperate Lowlands* of the Northern Plain (Siberia) varies from 10 inches in the south (on the desert margin) to 25 inches in the north. Most of the rain falls in thunder showers in the summer months, when low pressures over the interior allow cyclonic storms to travel inland. In winter precipitation is in the form of snow. The *Arctic Coast Lands* have a low rainfall, as owing to their low temperatures there is little evaporation and the atmosphere is dry.

NATURAL VEGETATION AND CROPS

The effect of climate and relief is well illustrated by the vegetation. In the north the period of active plant growth is limited to three

months: in the south-east it is continuous throughout the year. Irrigation is necessary for cultivation in the Desert Lands owing to lack of rain; and in the Monsoon and Mediterranean lands owing to its seasonal nature (Fig. 168).

The Tundra stretches along the northern shores of the continent.

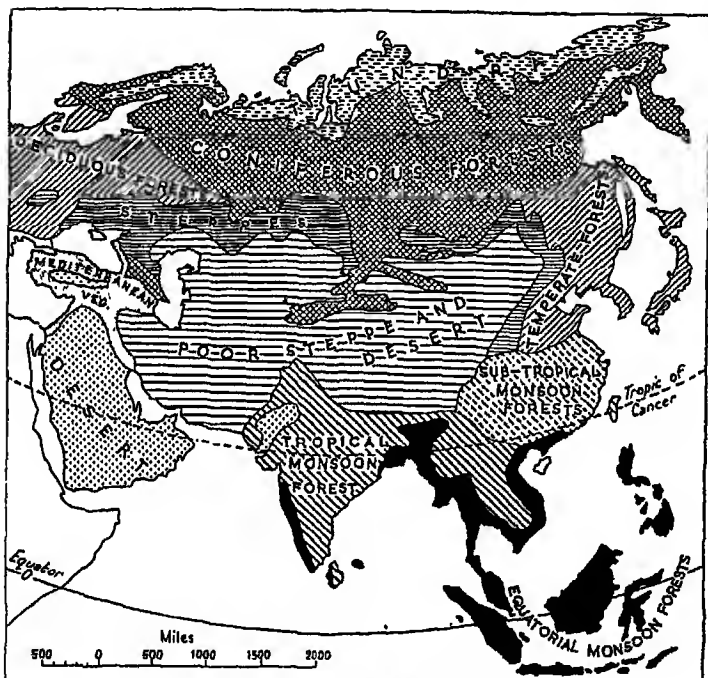

FIG. 168. Asia: Natural Vegetation.

The Coniferous Forest Belt, or Taiga, to the south of the Tundra, extends from the north of Europe across northern Asia to the Pacific. The chief trees include spruce, silver-birch, larch, and pine.

Deciduous Forests of broad-leaved trees, such as oak, beech, and camphor, lie to the south-east of the Coniferous Forest Belt.

The Steppes which are found to the south-west of the Coniferous Forests extend southward towards the Caspian, and through Europe to the Black Sea. The rainfall is sufficient for grass, and in the

wetter areas for wheat, but except in favoured districts, such as river valleys, it is insufficient for trees.

In the *Mediterranean Zone* plants are adapted to withstand the summer drought (see p. 242).

The *Desert Belt* is fertile where it can be irrigated. The steppe margins, e.g. Turan, are the home of herdsmen.

The vegetation of the *Mountain Belt* of Central Asia varies with

FIG. 169. Asia: Major Regions.

the elevation, ranging from monsoon forests to perpetual snow above 16,000 or 17,000 feet.

The *Monsoon Lands* are the most productive parts of Asia. In many parts are forests and jungles, but they are more open than the tropical forests, and most of the trees shed their leaves in the dry season. Teak and bamboos are important. In areas with less rain are wooded grasslands that resemble the savannas of South America. Rice, millet, cotton, sugar-cane, tea, and rubber are the chief cultivated crops.

In the *Equatorial Monsoon Forests* of Malaya and the East Indies trees grow more closely together than they do in the monsoon forests of India, but many of the products are similar to those of the monsoon region proper. Rubber is the leading commercial crop.

MAJOR REGIONS

We may divide Asia into four Major Regions based mainly on climatic characteristics which, as we have seen, are greatly influenced by the relief and especially by the central mountain barrier of the continent.

(1) *The Monsoon Lands* of the South-East include India and Pakistan, Indo-China, Malaya, the East Indies, China, Manchuria, and Central and Southern Japan.

(2) *The Mediterranean Lands* comprise Turkey (Asia Minor), Syria, Lebanon and Israel.

(3) *The Arid Lands* may be divided into (a) those of the *South-West* consisting of Arabia, Iraq, Iran (Persia), and Afghanistan; and (b) *Central Asia* including Chinese Central Asia and Soviet Central Asia.

(4) *The Northern Lowlands* and the *Arctic Coastlands*.

EXERCISES

1. Illustrating your answer by a sketch-map, describe the Central Mountain System of Asia.

2. Give an account of the structure and relief of the coast lands and islands of Eastern Asia. Show how they have facilitated communications by sea in this area.

3. Draw a sketch-map of Asia. Shade the high land, and on your map insert and name the Ob, Yenisei, Lena, Amur, Hwang-ho, Yangtze-kiang, Mekong, Menam, Salween, Irrawaddy, Ganges, Brahmaputra, Indus, Tigris, and Euphrates.

4. (a) What do you understand by a region of *inland drainage*? (b) Show by means of a sketch-map the Inland Drainage Area of Asia including the Caspian region. (c) Give examples of similar areas in other parts of the world.

5. What do you understand by a monsoon climate? Divide the monsoon region of Asia into three climatic divisions and give reasons for your divisions. Show by a sketch-map the direction of the winds over South-East Asia during the summer monsoon. Name two other regions, outside Asia, which have a monsoon climate.

6. On a sketch-map of Asia mark and name the chief Natural Vegetation Belts. Describe and account for the vegetation in any two of them.

7. Divide Asia into Major Regions, stating briefly the reasons for your divisions. Which region do you consider the most important, and why?

CHAPTER XVIII

THE MONSOON LANDS

INDIA AND PAKISTAN : GENERAL SURVEY

A Sub-Continent. In August 1947 India became independent of Britain, and there came into being two self-governing countries, now the Republics of India and Pakistan. But though the name *India* is applied to one only of these political units, it is convenient to retain it when dealing with this area as a major geographical region, which, besides India and Pakistan, includes the Himalayan states of Nepal, Bhutan, and Sikkim, and also Ceylon. Geographical India is aptly termed a sub-continent, for lofty mountains almost cut it off from the rest of Asia; it has an area of 1,700,000 square miles; its relief and climate are varied; and its 540 million people differ in race, religion, and language.

Structure and Relief. We may divide geographical India into three main physical divisions: (1) the Mountains of the North and North-West; (2) Peninsular India; and (3) the Indo-Gangetic Plain.

(1) **The Mountains of the North and North-West.** The Himalayas with the Pamirs, Hindu Kush, Sulaiman, and other ranges form a mountain wall shutting off the great sub-continent of India from the rest of Asia. When we remember that the Himalayas themselves extend for 1,500 miles, that the average elevation of their higher ranges is 18,000 feet, and that they vary in width from 300 miles in the west to 150 miles in the east, then we begin to realize the formidable nature of this mountain barrier whose height and breadth exceed that of any other in the world. Between the great fold-ranges lie longitudinal valleys so deep and inaccessible that they are useless as routes. The main chain of the Himalayas, rising south of the Indus and Brahmaputra valleys, culminates in such peaks as Everest (29,028 feet), climbed, May 29, 1953, by Hillary and Tensing of Col. Hunt's British Expedition, and Kinchinjunga (28,146 feet). On its southern side this main chain descends steeply through the sub-Himalayan chains to the Indo-Gangetic Plain.

The Tibetan Plateau, north of the Indus and Brahmaputra

valleys, is crossed by numerous fold ranges. North-east of the Indus valley rise the Karakorams, which form the divide between the streams flowing into the Indus and those forming part of the inland drainage region. Among the many peaks in the Karakorams is K₂, or Mount Godwin-Austen (28,250 feet), the second highest peak in the world.

It is not surprising that the passes across the Himalayas are high—numbers approach 17,000 feet—and that the valley-routes are

FIG. 170. Land Routes into India and Pakistan.

difficult. For centuries the passes were used by caravans trading between India and Tibet, but at the present time there is virtually no trans-Himalayan trade. Study the position of the chief passes on the map (Fig. 170). (1) From Darjeeling a route runs through Sikkim to the Chumbi valley and thence across difficult country to Lhasa, the capital of Tibet. (2) Farther west the road from Hindustan winds up to Simla, set amidst pine woods and gardens, whence it continues to Gartok, in the west of Tibet. (3) From Rawalpindi (Punjab) the road runs up the Jhelum valley to Srinagar, the capital of Kashmir, from which (4) a difficult route leads to Leh, on the upper Indus; thence to the Shyok valley which it ascends to the Karakoram Pass (18,290 feet), whence it is continued to the Tarim Basin.

South of the Hindu Kush, the Sulaiman and Kirthar Mountains rise steeply from the Indus lowlands. This mountain wall, much lower than the Himalayas, is crossed by three relatively easy passes.

(5) The *Khyber* (3,400 feet), the route by which most of her conquerors entered India, leads from Peshawar to Kabul, the capital of Afghanistan. (6) South of the latter pass is the Gomal Pass leading from the Punjab to Ghazni. This route, one of the oldest of all trade routes, passes through the wild district of Waziristan, inhabited by hardy Waziris. (7) The *Bolan Pass* (5,900 feet), between the Sulaiman and Kirthar Mountains, is followed by the railway from the Indus valley to Quetta, the capital of Baluchistan, whence it is continued to Zahidan (Duzdap).

(2) **Peninsular India.** South of the Indo-Gangetic Plain the greater part of the country is occupied by an old crust-block forming the plateau of Peninsular India (Fig. 181). On the west this plateau is margined by the Western Ghats (steps) whose steep escarpments rise above the narrow plains of the Malabar Coast, nowhere more than 50 miles wide. Towards the east the more broken Eastern Ghats descend gently to the wider lowlands of the sandy, surf-beaten, and harbourless Coromandel Coast. On the north-west the plateau extends to the Aravalli Hills, beyond which the Thar Desert bars the way to the Indus lowlands.

East to west ranges, crossing the northern part of the plateau, render communications difficult between north and south. They include the Vindhya Hills to the north, and the Satpura Hills and the Mahadeo Hills to the south of the Nerbada valley. The line of the two latter ranges is continued east by the Maikal Mountains. The Nerbada and Tapti flow west to the Gulf of Cambay. The Tapti valley is followed by railways leading (i) to the plateau and (ii) through the Khandwa Gap to the Nerbada. South of the Tapti the Western Ghats form a barrier between the Malabar Coast and the interior. The only easy route lies in the south where it traverses the Palghat Gap, between the Nilgiri and Anaimalai Hills.

The Mahanadi, Godavari, Kistna, Pennar, and Cauvery flow south-east across the plateau to the Bay of Bengal. In their upper courses they speed through deep inaccessible gorges descending by falls, some of which, like those on the short swift streams flowing down the Western Ghats, are harnessed for hydro-electric power. In their lower courses the rivers flowing into the Bay of Bengal form deltas, at the head of which dams have been built to store water for irrigating the rice fields of the lowlands.

Though the term 'Deccan Plateau' is often applied to the whole of the upland area of Peninsular India, strictly speaking it includes only the western part of the region, stretching from the Tapti valley southward to the Nilgiri Hills. In geologically recent (Tertiary) times many outpourings of lava, from enormous earth fissures, spread over the north-west of the Deccan to form one of the most extensive and thickest accumulations of lava-flows in the world. The basaltic rocks have weathered to form a rich black soil, retentive of moisture, and so well suited to cotton that it is often termed black cotton soil. It presents a great contrast to the red laterites found elsewhere on the plateau. Laterite soils dry out easily and when cultivated need irrigating. They are rather infertile, since, owing to leaching, soluble plant foods, e.g. potash, are removed from the top soil, leaving alumina and iron oxides, the latter accounting for their red colouring.

FIG. 171. Irrigation.

(3) **The Indo-Gangetic Plain or the Plain of Hindustan.** Between the great fold-mountains of the Himalayan system and the old crust-block of Peninsular India is the *Plain of Hindustan*, one of the most productive and thickly peopled lowlands in the world. This vast depression, an arm of the sea that has been filled up with sediment brought down by the Indus, Ganges, Brahmaputra, and their tributaries, is constantly being replenished by silt transported by rivers and spread over the land during floods. The deep alluvial soil is remarkably fertile, but agricultural production depends on the amount of water available, whether obtained directly from rain or by irrigation. Here it may be noted that irrigation is necessary in many parts of India not because the annual rainfall is small but because of its seasonal nature. A low divide, rising to scarcely 1,000 feet, which connects the Himalayas with the plateau to the south, separates the basin of the Indus from that of the Ganges.

After leaving the Himalayas, the *Indus* enters the Punjab, 'the Land of the Five Rivers', where it receives the Jhelum, Chenab, Ravi, Beas, and Sutlej. In spring these streams trickle over broad boulder-strewn beds, but in summer, fed by melting snows of the Himalayas, they form wide, deep rivers whose waters bring fertility to the thirsty land. In its lower course the Indus, like the Nile, receives no tributaries. It flows between the Thar Desert and the Kirthar Range (marking the eastern edge of the Plateau of Baluchistan), and enters the Arabian Sea by a delta.

The *Ganges* rises on the southern slopes of the Himalayas from which it receives the Jumna, the Gogra, and other snow-fed streams. Its chief right-bank feeders are the Chambal and the Son. The *Ganges* has been pushed south by its Himalayan affluents, which are swifter, greater in volume, and more numerous than the rivers descending from the plateau on its south. The silt-laden waters of the Brahmaputra have united with those of the *Ganges* to form a vast delta, crossed by many distributaries, which is steadily advancing into the Bay of Bengal.

Weather and Climate. Nowhere else in the world is the monsoon climate so well marked as in the Indian sub-continent, and in no other region of similar size do so many people depend for their prosperity on climatic conditions. In most parts of India there are three seasons: the cold season from October to March; the hot season from April to mid-June; and the rainy season from mid-June to October. The term 'cold' is a relative one. In the south of India temperatures during the cool season resemble those of the Mediterranean Lands in early summer. In the Indo-Gangetic Plain, January temperatures are about the same as June temperatures in the south of the British Isles. Elevated regions, like the Vale of Kashmir, have a temperate climate: the winters are considerably colder than in the British Isles, but the summers are hotter.

The Cold Season. From October to January temperatures decrease, while air-pressures increase from the south to the north-west of India, which is the centre of a high-pressure system. Towards the end of October the winter monsoon winds start blowing over India from the high-pressure areas over the land towards the areas of low pressure over the sea. Except where they have crossed the sea, they are dry winds. They blow mainly from the north-east, but in the

Ganges valley they come from the north-west. The north-east winds, which gather moisture as they pass over the Bay of Bengal, bring rain to the south-east of India. North-West India also receives some rain during the cool season from depressions coming from Iran and Afghanistan. Apart from the south-east and north-west, the greater part of India receives little rain during the cold season. The skies are cloudless, the days brilliantly sunny, and even in the

FIG. 172. Asia: The Winter Monsoon.

rainy areas there is far less cloud and more sunshine than there is on an average summer day in the British Isles.

The Hot Season. As the sun moves northward towards the Tropic of Cancer temperatures rise and pressures diminish. In May the hottest area, and that with the lowest pressure, lies over the Deccan, but by June the low-pressure system has moved north and is centred over the Indus lowlands and Baluchistan. The heat is intense and by the beginning of June is in the plains almost unbearable. There is a considerable daily range of temperature, and the nights are hotter than very hot summer days in England. The south-west of India receives rain in April and May, as does Assam, where it is of great importance for the tea crop; but with these exceptions the rainfall throughout India is negligible.

The Rainy Season. Towards the end of May winds blowing from

the south and west cause violent storms, with heavy showers, which are repeated every few days. These storms herald the south-west monsoon—the rain-giver of India—which ‘bursts’ about the middle of June, when rain descends upon the parched earth in torrential downpours accompanied by thunder and lightning. The south-west winds, blowing across the Arabian Sea, cause heavy rain on the windward slopes of the Western Ghats and the strip of the Malabar

FIG. 173. Asia: The Summer Monsoon.

Coast at their base, both of which have over 80 inches of rain per annum. But the Deccan Plateau, on the leeward side of the Western Ghats, receives only a moderate rainfall (about 40 inches per annum), while the belt near the eastern foot of the Ghats, lying in the rain shadow of the mountains, has 30 inches or less a year. The south-west of the tableland is better watered: it receives rain both from the south-west and the retreating north-east monsoon, and the dry period is limited to two or three months.

South-west monsoon winds, blowing across the Bay of Bengal, cause an extremely heavy rainfall (over 80 inches per annum) on the windward slopes of the mountains in Burma and Assam. Other monsoon winds from the Bay, reinforced by south-west winds from the Deccan, blow up the funnel-shaped Ganges valley, causing heavy rain along the eastern windward slopes of the Himalayas and the

plains at their base (over 80 inches). But these winds lose most of their moisture as they travel up the valley and reach the Punjab as dry winds. Calcutta has an annual rainfall of 59 inches compared with 18 inches at Lahore: in both cases the bulk of the rain falls during the summer monsoon. The south-west monsoon winds, blowing towards north-west India, are relatively dry, for they have not crossed a large expanse of ocean. Some blow up the Indus valley, but most are deflected to the north-east along the margin

of the Deccan, leaving the Thar Desert between the Indus and the tableland of Peninsular India.

'After four to six weeks of heavy rain, often falling uninterruptedly for two or three days in succession, the weather clears up, and sometimes some weeks pass without further rains; after which a week or two of more wet weather brings the rainy season to a close.'¹ Owing to the presence of clouds temperatures are, as a rule, less than in the preceding hot season, but with the clearing of the skies towards the end of the rains they tend to rise somewhat for a short time. Upon the rain, brought by the south-west monsoon, millions of farmers depend for their livelihood. Occasionally in some districts—but never in all—the monsoon fails, with the result that famines occur.

Natural Vegetation. This is conditioned partly by the relief, but more especially by the climate, particularly the amount of rain and its seasonal duration. And in certain regions, such as the Ganges Valley, it has been greatly modified by Man.

¹ *The Climates of the Continents*: Kendrew (Clarendon Press).

The southern slopes of the Himalayas, especially the eastern and central portions, receive heavy rains during the summer monsoon. At the base of the mountains stretches a tropical belt, the Terai, some 20 miles wide, where rather open forests, composed chiefly of sál trees, are intermingled with marshy jungles, and grass-lands with

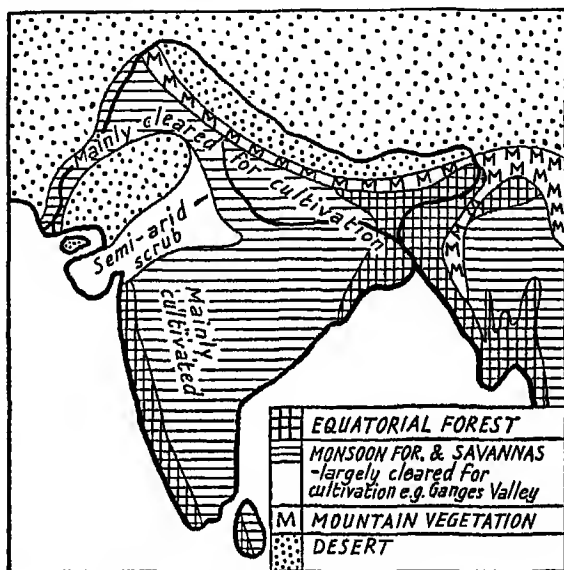

FIG. 175. Sub-continent of India: Vegetation.

giant bamboos and palms. In the cooler regions from 3,000 to 6,000 feet the trees resemble those of temperate lands. In April and May magnolias and rhododendrons—as large as English horse chestnuts—are in bloom. From 6,000 feet the chief trees are deodars and oaks, while in sheltered valleys grow apples, pears, chestnuts, evergreen oaks, laurels, and maples. These are succeeded by pines, larches and other conifers which grow up to 12,000 feet. Above this height the trees become stunted, passing into Alpine pastures, in spring and early summer bright with flowers like poppies, gentians, and edelweiss. Higher still are tundra which, between 16,000 and 17,000 feet, merge into the region of perpetual snow.

From early times the Ganges valley has been so intensely cultivated that its original vegetation has disappeared and it is now practically treeless. It seems probable that this lowland was once covered with open forests of the savanna type. Very different are the Sundarbans, the impenetrable jungles and tidal mangrove swamps, which cover the seaward portion of the Ganges-Brahmaputra delta.

Owing to the low rainfall of the Punjab, the natural vegetation consists mainly of evergreen scrub with deciduous woodlands in some of the more favoured areas, and trees along the banks of rivers and canals. The prevailing vegetation in the arid lower Indus basin consists of scattered herbage dotted with thorny scrub (acacias and tamarisks); but palm trees thrive in the oases, and lines of trees often margin the watercourses, which are dry for most of the year.

Forests still cover considerable areas in Peninsular India. Owing to the heavy rainfall (over 80 inches per annum) luxuriant forests with coco-nut palms (especially in the maritime districts) are found along the Malabar Coast; while the windward slopes of the Western Ghats are also thickly wooded. Very different is the Coromandel Coast, where, owing to the lower annual rainfall (under 40 inches), long stretches are covered with evergreen jungle which, however, gives way in the deltas to fertile irrigated tracts—veritable oases—usually planted with rice. On the plateau itself rainfall also provides the key to the natural vegetation. Broadly speaking, the north-west has less rain than the south-east, and the driest portion is the belt lying in the rain shadow of the Western Ghats. Despite cultivation, much of the original vegetation remains. In districts where the annual rainfall does not exceed 80 inches, but is more than 40 inches, there are open monsoon forests, with teak and other deciduous trees which shed their leaves in the dry season. But such forests are by no means continuous and are interspersed with stretches of scrub, while a further contrast is provided by the densely wooded river valleys.

PEOPLES OF THE INDIAN SUB-CONTINENT

Race, Religion and Language. A dark-skinned people, known as Dravidians, are regarded as the aborigines of India, but the great variety of racial types found among the peoples is due to the many migrations into the sub-continent that have taken place during the past 5,000 or 6,000 years. Recent excavations in the Indus valley

have shown that as early as 3000 B.C. India was the home of a civilized people, who lived in well-planned towns, practised agriculture, and were skilled craftsmen. Meanwhile in the north-east Mongolian tribes filtered into India and mingled with the people there. The centuries rolled by. Then, about 1500 B.C., Aryan-speaking tribes from Central Asia streamed into India through the Khyber and other north-west passes. They imposed their culture on the civilization they found there, and from the combined material arose 'the philosophy, religion, art, and letters that were the glory of ancient India'.¹

From the eleventh to the sixteenth centuries there poured into India, again through the north-west passes, Turkish, Afghan, and Mongol invaders, who, with fire and sword and preaching Islam, occupied the Indus lowlands and swept through the Ganges valley and also into Peninsular India. These Mohammedan incursions culminated in the foundation of the Mogul Empire, which reached its zenith under Akbar, a contemporary of Elizabeth I of England.

It was Elizabeth who, on the last day of the year 1600, granted a charter to the British East India Company, founded about the same time as the French and Dutch East India Companies. The early European settlements in India, first by the Portuguese and later by the French and the British, aimed not so much at acquiring territory as at securing trade. During the eighteenth century there were fierce struggles between the British and the French for supremacy in India, but the former were the victors. In 1858, a year after the Indian Mutiny, the control of India passed to the British Crown, and for the first time in its long history the country was united under one ruler. The extension of British authority over the whole of India made possible the building of roads and railways, and the construction of those large-scale irrigation works which have so greatly benefited the country. It also facilitated the spread of the English language, which became the common tongue of well educated people.

Religions. In no other area of comparable size do religious differences play so great a part in everyday life as in India, where religion rather than race is the dividing factor. Out of the entire population of geographical India less than 2 per cent. are Christians, and a few are Buddhists or Parsis, but 70 per cent. are Hindus and 21 per cent. are Muslims (Mohammedans).

¹ Based on *Census of India*, vol. i.

Hinduism is one of the oldest of all religions. Its most striking feature is the idea of *caste*. A Hindu believes that every man is bound to the caste, or class, in which he is born. The four great divisions of castes are the *Brahmins*, to which all priests belong, though all Brahmins are not priests; the *warriors*; the *farmers* and *craftsmen*; and the *labourers*. Attached to the Hindu community are the 'outcasts', now termed the Scheduled Castes, who once suffered grave social disabilities. But rigid caste distinctions are being broken down, especially in the towns, as a result of travel, intermarriage, and more liberal thinking.

Islam, the other great religion of the Indian sub-continent, is strongest in the north-west and in Eastern Bengal. Muslims and Hindus have little in common. Indeed, so deep is the gulf between them that when India became independent it was found necessary to divide British India into two states, since the Muslim minority feared that they would not receive fair treatment from the Hindu majority once British control was relinquished.

Languages. About 225 languages are spoken in the sub-continent, but the chief ones are limited to about 15. English is understood by many educated people. The main languages are derived either from Sanskrit or belong to the Dravidian family. The former include Hindi, widely spoken in the Indian Republic; Bengali used in West Bengal and East Pakistan; Urdu, the main language in West Pakistan; Punjabi, Marathi, and Gujarati. The Dravidian languages of Tamil, Telugu, Kannada, and Malayalam are common in the south of India.

Government. Under British administration India was divided into (i) *British India*, which consisted of a number of Provinces enjoying a large measure of self-government, and (ii) the *Indian States*, whose rulers owed allegiance to the King-Emperor, represented in India by a Viceroy. When British rule in India ceased, British India was partitioned between the Dominions of India and Pakistan: and ultimately the Indian States joined one or the other of these Dominions, but in doing so most of them ceased to exist as separate units. In 1950 India became a Republic, and in 1956 Pakistan followed suit, but both countries are still members of the Commonwealth.

Distribution of Population. Though the Indian sub-continent contains many big cities, yet over 80 per cent. of its 540 million people dwell in villages, and 75 per cent. depend on farming for their living. Rainfall and relief provide the keys to the distribution of

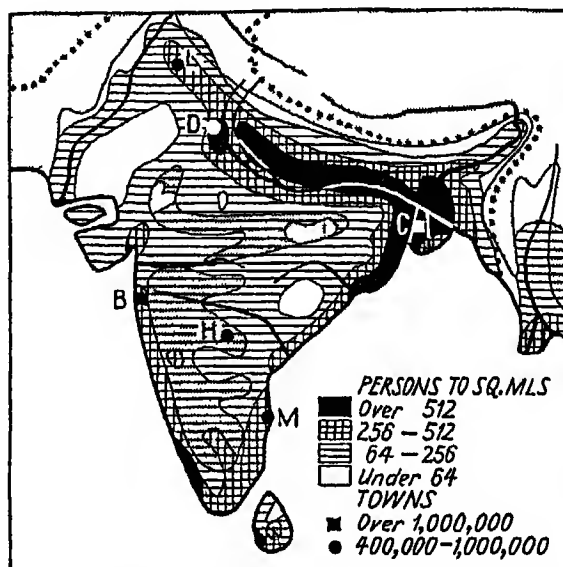

FIG. 176. India and Pakistan : Distribution of Population.

population. The most highly productive and consequently the most thickly peopled regions are plains receiving a heavy rainfall. Thus in the Ganges valley and delta, and notably in East Pakistan with over 776 persons to the square mile, the population is extremely dense, as it is also on well watered coastal lands like those of Kerala in the south-west, where there are over 1,000 persons per square mile. The most sparsely peopled areas are those, such as Rajasthan, which receive little rain and cannot be widely irrigated; and mountainous regions like Kashmir where, despite the invigorating climate, the rugged relief prohibits close settlement.

THE REPUBLIC OF INDIA

The Republic of India has an area of well over a million square miles, and a population of 438 millions, which is increasing at an average rate of about 3 millions a year. As we have already seen, the great majority of the people are peasant cultivators. Most of

FIG. 177. The Sub-continent of India: Main Physical Divisions.

them are very poor, and more than half have scarcely enough to eat because the amount of food grown in the country is quite inadequate to the demand. The most urgent problem facing India is how to support her people in a country where production does not keep pace with population. How can this state of affairs be remedied? As there seems to be no prospect of a decrease in the number of people, and as there is little possibility of mass emigration, it would appear necessary to (i) increase the amount of land under large-scale irrigation; (ii) improve the yield per acre by introducing more scientific methods of farming; and (iii) step up exports of cash crops and manufactured goods, and so obtain funds with which to import essential foodstuffs.

Calcutta (3 millions), 80 miles up the Hugli distributary of the Ganges, the outlet for the Gangetic Plain, is linked by rail with all parts of India. From Calcutta-Howrah lines run up the Ganges valley to Patna, important for rice, near the confluence of the Son and the main stream; past *Benares*, Holy City of the Hindus, standing high on the left bank of the Ganges, and thence to *Allahabad*, placed where the Jumna enters the main stream. From Alla-

FIG. 179. Distribution of Rice.

FIG. 180. Distribution of Cotton.

habad a line goes south-west to Bombay, another runs up the valley to *Cawnpore*, with cotton, flour, and jute mills, north-east of which is *Lucknow*. Continuing up the valley the railway from Cawnpore passes through *Agra* to *Delhi* (2,610,000), the capital of India, on the right bank of the Jumna. The fact that it is a great railway and air junction draws attention to the importance of Delhi as a focal point, almost equidistant from Calcutta, Bombay, and Karachi. The historic city lies athwart that route from the Indus lowlands to the Ganges valley, passing between the Thar Desert on the south and the Himalayas on the north, which was followed by invaders entering India through the north-west passes. New Delhi, the seat of the Government of India, lies some miles south of Old Delhi.

The Plateau and its Margins. This region, lying wholly within the Republic, is more difficult of access than the Gangetic Plain, and population tends to be concentrated round its margins rather

than in the interior. Crops include cotton, millet, and oil-seeds. *Cotton* is grown in Gujerat, east of the Gulf of Cambay, but the principal area is found in the north-west of the Deccan. Here the deep black and rather heavy basaltic soils by holding the moisture from the monsoon rains make irrigation unnecessary for cotton

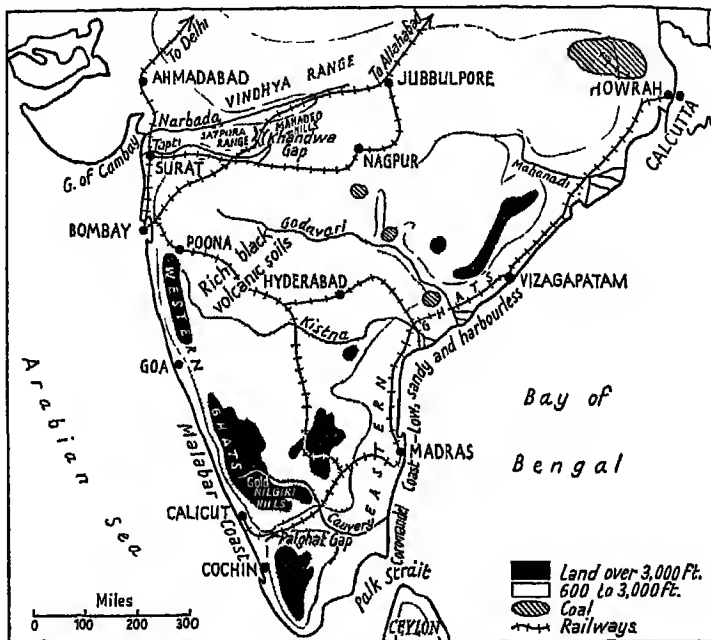

FIG. 181. Peninsular India.

growing; but the 'going' is hard, and sometimes six yoke of oxen are needed to draw the lumbering ploughs used to break up the heavy clods. The Deccan cotton crop is mainly of the short-staple variety and is not of a very high quality.

Millet is widely cultivated as a food crop in the drier parts of the Peninsula. The seed is ground into flour; the stalks provide fodder for cattle; the straw is used for making fences, and when plastered with mud yields material for building the walls of huts. Of the many pulses the chief is *gram* or chickpea, which besides being a valuable food grain also fertilizes the soil. *Ground-nuts* and *oil-seeds*

(linseed, castor, and sesame) are important crops in the drier areas. Both yield oil, at one time used mainly for lighting and heating, but now widely produced for export, as it is in great demand by manufacturers of soap and margarine. Some *wheat* is cultivated as a cool season crop in the north of the plateau, but south of the Tapti and Mahanadi valleys temperatures are too high. A certain amount of *coffee* is grown in Mysore, and *tobacco* is also cultivated in this state, Kerala, and Madras.

Rice is the chief crop in the lowlands. In the deltas along the Coromandel Coast three crops are produced each year on land irrigated by canals, and also (notably in parts of Madras State) by means of water drawn from wells.

The 16-mile long Hirakud Dam across the Mahanadi is the greatest of a number of dams built to provide water for hydro-electric power and perennial irrigation. But in many parts of the plateau it is not possible to construct large-scale irrigation works as the rivers flow in steep valleys far below the general surface level. Water for irrigation is obtained mainly from tanks, reservoirs varying in size from ponds to lakes several square miles in area. They are made by building mud dams across the valleys of small streams depending for their water on the monsoon rains. This method is widely practised in the southern Deccan.

Bombay stands on an island beside the only natural deep-water harbour on the west coast of India. Its development began with the building of railways to the interior, and the opening of the Suez Canal which greatly lessened the distance to Europe by sea. Greater Bombay, with a population of 4 million, is the second largest city and second most important industrial centre in India. As its hinterland includes the cotton-growing area of the Deccan, it is the chief port in India for the export and manufacture of cotton. Behind the city rises the steep escarpment of the Western Ghats, up which two rail-

FIG. 182. Site of Bombay.

way lines wind their way on to the tableland. One line runs south-east through *Poona* to Madras; the other north-east to the Tapti valley, where the branch to Calcutta continues up the valley making for *Nagpur*; and that to Allahabad runs through the Khandwa Gap to *Jubbulpore*, a town with large railway works and cotton mills. The line to Delhi runs north along the coast through Surat, a few miles up the Tapti, with cotton, rice, and paper mills, to *Ahmadabad* ($1\frac{1}{2}$ million), a cotton-manufacturing town, 50 miles north of the head of the Gulf of Cambay. *Madras* ($1\frac{3}{4}$ million), with an artificial harbour, is the fourth largest city in India, but as a port it ranks far behind Calcutta or Bombay. Its exports include groundnuts, hides, and cotton. Note the railway running in a south-westerly direction from Madras, through the Palghat Gap, to the port of *Calicut*. Almost midway between Calicut and Bombay is the former Portuguese colony of *Goa*. The ports of *Cochin*, south of Calicut, and *Vizagapatam*, on the east coast, which builds ships, are rapidly growing in importance.

Mining and Manufacturing. India has ample supplies of coal and more than enough iron ore and manganese to supply her growing iron and steel industries. The chief *iron* mining areas lie along the Bihar-Orissa border where *manganese* is also mined. The major *coal-fields* are found in the Damodar valley of Bihar and West Bengal, where the principal mining centres are Raniganj, Asansol, Jharia, and Bokaro. The Damodar fields supply coal to iron and steel plants at Asansol, Durgapur (a new plant on the edge of the coal-field), and Jamshedpur, 140 miles west of Calcutta. *Bauxite* deposits, worked along the Bihar-Madhya Pradesh border, supply raw material for aluminium works at Sambalpur, which depend for hydro-electric power on the nearby Hirakud Dam. On the Kolar gold-field (Mysore) the machinery in the mines is electrically driven by power from the Krishnarajasagara Dam, on the Cauvery. *Mica* is mined in northern Bihar and Madras State.

During the last decade vast strides have been made in industry. Besides iron and steel, heavy industries include the manufacture of cement and chemicals, e.g. in the Damodar valley where electricity, dependent on both coal and hydro-electric

power, is being widely developed. Apart from heavy industries, the chief manufactures are those concerned with textiles, e.g. cotton at Bombay, and jute at Calcutta, where the mills draw much raw material from East Pakistan. Many people are employed in tea factories (e.g. in Assam). Others work in sugar and oil (vegetable) refineries, and rice mills.

Traditional handicrafts carried on in the villages give employment to vast numbers of people. Of these cottage industries cotton-spinning and weaving are the most important, for cotton is the chief fibre crop and *saris* and other garments are usually made from it. Silk and wool are also manufactured: the fleeces of sheep and goats are used for making carpets and blankets. Other handicrafts include the making of pottery, leather goods, and metal goods.

Trade. India's chief *exports* are (i) tea (see p. 282); (ii) *jute products*, e.g. gunny (sacking), much being shipped to the United States, and sacks, sent mainly to Australia; and (iii) *cotton goods* of the cheaper kinds, which find a market in other parts of Asia. First among *imports* comes *grain*, both *wheat* and *rice*. This is followed by *machinery*, of which much is needed for factory development, and *raw cotton* to supplement home supplies. India carries on more trade with the United Kingdom than with any other country, and it is as a customer rather than a supplier that the United Kingdom is important. Next comes trade with the United States.

PAKISTAN

We have seen that when British rule ended in India, the main reason for setting up a separate state of Pakistan was a religious one. Today nearly the whole population in West Pakistan is Muslim, though in East Pakistan about a third is still Hindu; these two areas are nearly 1,000 miles apart. Pakistan has a total area of 365,000 square miles and a population of 94 million. Like the Republic of India, it is primarily an agricultural country, and it ranks second only to its neighbour in the area under irrigation. Recently there has been an increase in the output of cottage industries, and also in factory production.

West Pakistan is nearly six times the size of East Pakistan, but its population is only about five-sixths that of the latter area. It

comprises the greater part of the Indus plains, and includes the arid Plateau of Baluchistan, separated from the lower Indus Plain by the Kirthar Mountains. The most populous part of West Pakistan is the Punjab, where, though the annual rainfall is low (Lahore 19

FIG. 183. West Pakistan.

inches), an area as large as Wales has been made productive by cutting irrigation canals, fed by the Indus and its five great tributaries. Barrages, built where the rivers leave the hills, hold back water used for perennial irrigation by canals running at a lower level. In some parts inundation canals are led off direct from the rivers, so as to utilize their waters during the flood season. In the Punjab irrigation from wells is common in districts near the foot of the mountains, where water lies relatively near the surface.

Wheat, barley, millet, pulses, and linseed are among the chief cool-season crops, which are harvested in March and April. The

21. A TOWN IN THE INDIAN REPUBLIC—IRRIGATION IN PAKISTAN

(Above) A town in Rajasthan. Note the temple (left), the flat-roofed houses, and the humped cow. Rajasthan is one of the most arid states in the Republic of India; part of it lies in the Thar Desert. (Below) The Sukkur Barrage across the Indus, which holds back water to irrigate Sindh, Pakistan (see p. 289).

22 MOUNTAIN SCENES IN INDIA AND PAKISTAN

(Above) A Tea Plantation in Assam where the slope provides that natural drainage required for the successful cultivation of the crop. The tea-growing area extends westward to Darjeeling, along the foothills of the Himalayas which here may be seen in the distance. Note the factory to which the leaves are taken to be withered, rolled, fermented, dried, and graded before being packed in chests for export (see p. 287). (Below) Pack-mules passing through the Khyber Pass, the grim defile, 33 miles long, through which most invaders entered

rainy season crops, gathered from October to December, include cotton and sugar-cane. High-grade American cottons have been introduced into the Punjab and Sind where they do well on irrigated lands. Thus in the Indus lowland, as in most parts of India, there are two harvest periods. Directly the sun-baked ground is moistened, by rain or irrigation, the work of the *ryot* (peasant) begins and is incessant until the harvest is gathered. The blade as it appears above the ground must be guarded from stray cattle, wild pigs, deer, and monkeys; while later, when crops such as cereals begin to ripen, they must be protected from flocks of birds, especially parrots. As soon as grain is brought in from the fields it is threshed by bullocks or cows, which trample on it as they are driven round and round the clay threshing floors. The winnowing is done by throwing the mixed grain and chaff into the air, when the wind blows away the chaff and allows the heavier grain to fall to the floor.

In the lower Indus basin the annual rainfall is negligible (Karachi 8 inches), and cultivation depends entirely on irrigation. But what was formerly an arid region has been made productive by the building of the Sukkur Barrage across the Indus, which stores water to feed a network of canals used to irrigate 9,000 square miles, devoted mainly to growing winter wheat and cotton. Farther down the Indus a barrage, near Kotri, provides water for irrigation and power.

Some coal is mined, and there is a small oil-field, but more important is natural gas piped from Sui to Karachi and also to Multan to supply power for industry.

The main outlet for West Pakistan is *Karachi* (2,000,000), the former Federal Capital of Pakistan. Lying to the west of the Indus delta, it exports cotton (mainly of the short staple type) as well as raw wool, hides, and skins. From Karachi the railway runs up the Indus valley to *Hyderabad* (Sind), and on to *Sukkur*, whence a line runs north-west through the Bolan Pass to *Quetta*, the capital of Baluchistan. The main railway from Sukkur continues up the valley to *Multan*, and thence follows the Ravi valley to *Lahore* (1,300,000), the capital of West Pakistan, with flour mills, engineering shops, and textile factories. From Lahore railways go (a) north-west via *Rawalpindi*, the seat of the Federal Government of Pakistan, to *Peshawar*, commanding the Khyber Pass route, and (b) east across the frontier to Amritsar and Delhi.

East Pakistan comprises the eastern portion of the delta of the Ganges-Brahmaputra, from which it stretches northward to the foothills of Assam. Into its 54,134 square miles are packed 51 million people, mainly peasant farmers. Rice and sugar-cane are

FIG. 184. East Pakistan.

grown, and there are tea plantations in the northern hill-country. But the most valuable crop is jute, which thrives on marshy lowlands. Sown in March or April, it is ready for cutting in July. After the tough fibrous plants have been retted and crushed, they are spun and woven into gunny cloth. Raw jute is the chief export of Pakistan. Some is sent to mills at Calcutta: far more is shipped either through *Chittagong* or *Khulna*, a new inland port, which, like *Dacca*, the chief city of East Pakistan, stands on a distributary of the Ganges-Brahmaputra.

EXERCISES

In questions 1 to 7 India should be treated as a sub-continent.

1. India has three seasons. Name them and state their approximate duration. Describe the general weather conditions experienced during *one* of them.

2. (a) At what period of the year does the greater part of India receive its rain? (b) Name (i) *two* regions with exceptionally heavy rainfall, (ii) *one* with a light rainfall, and (iii) *one* with two rainy seasons. Account for the differences.

3. Why is irrigation necessary in India even in regions with a heavy annual rainfall? Describe the different types of irrigation practised in the country and state the principal areas in which each is carried on.

4. On a sketch-map of India indicate the major Natural Regions. Give a description of *one* of the more important regions under the headings: Relief, Drainage, Climate, Crops, and Towns.

5. Describe the distribution of population in India. Account as fully as you can for the facts you state.

6. *In India the term hut or house covers a variety of dwellings including portable screens of bamboo matting, thatched and mat-walled huts sometimes built on piles and sometimes in trees; the thatched-roofed, hog-backed huts of Bengal peasants; those with steeply pitched tiled roofs found along parts of the west coast; and the mud-walled flat-roofed houses of the Punjab.* Account for the type of hut found in (i) Bengal, (ii) parts of the west coast, and (iii) the Punjab.

7. (a) Name *two* food crops and *two* cash crops grown in India, and in each case name one important area of production. (b) Select *one* of the food crops and *one* of the cash crops you have named, and describe the geographical conditions that favour its production in the area you have mentioned.

8. Select *two* of the chief ports in the Republic of India and *one* in Pakistan. Summarize for each port *three* main factors which contribute to its importance as a seaport. Add for each port a sketch-map to illustrate the points specified in *your answer*. Include necessary names.

9. (a) Illustrating your answer by a sketch-map describe the distribution of mineral production in the Republic of India. (b) What advantages and what disadvantages has this country for large-scale manufacture?

10. (a) Describe the farming activities of the people of West Pakistan. (b) How do you account for the fact that there are approximately 775 persons to the square mile in East Pakistan compared with 105 to the square mile in West Pakistan?

CEYLON

Ceylon is a self-governing country of the British Commonwealth. Lying off the south-east of India, from which it is separated by Palk Strait, the island is splendidly placed almost in the centre of the Indian Ocean. Ceylon consists of a mountainous core surrounded by lowlands which are widest in the north. In structure it

resembles the Deccan. The rocks are mainly igneous, but the Northern Plain is composed of limestone, while red latcite soils (locally known as *kabūk*) cover considerable areas in the plains.

Owing to its maritime situation, and to the fact that it lies closer to the equator than India, the climate of Ceylon is more equable than that of its larger neighbour. On the lowlands temperatures are high and both the annual and daily range is small, but the highlands are pleasantly cool. The seasons are determined by the monsoons. The South-West Mon-

FIG. 185. Ceylon.

soon (April to September) brings rain to the south-west; the North-East Monsoon (October to March) first to the whole island but later to the eastern side of the hills only. At one time the whole of Ceylon was densely forested, but much has been cleared, and nearly one-fifth of the island is now cultivated.

We may divide Ceylon into two regions: (1) the Mountainous Region; (2) the Coastal Plain.

(1) **The Mountainous Region**—the 'Hill Country'—consists of lofty, much-dissected uplands, whose old hard rocks yield plumbago (graphite). There are numbers of quarries where sapphires, rubies, and other gems are obtained. The swift rivers are useless for navigation, but their waters are used for irrigation, especially in their lower courses. Tea and rubber, the chief cash crops, are grown on

well-watered but well-drained slopes in the south and south-west. The *tea* shrubs, which are planted in rows, do not reach their full yield till their sixth year. Most of the picking is done by women. The two young and tender leaves, together with the bud at the top of each stem, yield the finest tea. India and Ceylon are the leading tea-exporting countries, producing some 73 per cent. of the world's total export crop. Some cacao is grown at elevations between 1,000 and 2,000 feet. *Kandy*, the former capital, situated in the Hill Country, and connected by rail with Colombo, is famous for the Temple of 'The Sacred Tooth of Buddha'.

FIG. 186. Comparative Production of Tea for the Three Principal Tea-exporting Countries. 1. India; 2. Ceylon; 3. China.

(2) **The Coastal Plain** is widest in the north, where the porous limestone rapidly absorbs moisture from the rains. Much of the land in this area is covered with scrub, and agriculture is limited to areas irrigated from tanks which hold back water from the rains. *Jaffna*, a port, is the chief town of the northern lowland, which as a whole is thinly peopled. *Trincomali*, on a magnificent harbour on the east, lies off the main trade routes, and partly for this reason it is of little commercial importance.

Apart from the northern district, the coastal plain is well watered and fertile. Both rice—the staple food crop—and coco-nuts are widely cultivated, especially in the wet south-west. The many coco-nut plantations yield copra, coco-nut oil, desiccated coco-nut and coir, which products rank second in Ceylon's export list. Cinnamon is grown on the sandy soil of the south-west coastlands.

Colombo (426,000), the capital and chief port, is situated in the south-west on a splendid artificial harbour which provides shelter from the South-West Monsoon. Its position makes it an important

port of call on the route from Europe, via Suez, to the Far East, Galle, once the chief port of Ceylon, is now relatively unimportant.

The population of Ceylon is 8 millions. The Sinhalese, the most numerous race, may be divided into the 'Low Country' folk living on the plains in the west and south, and the 'Kandyans', who inhabit the hill country. In the north of the island live descendants of Tamils from Southern India, known as Jaffna Tamils to distinguish them from immigrant Tamil coolies who come from Southern India to work on the plantations. In many of the larger towns the traders are Moormen, descendants of Arabs who married Tamil women. The Sinhalese are Buddhists, the Tamils profess Hinduism, and the Moormen are Muslims.

FOREIGN TRADE OF CEYLON			
EXPORTS		IMPORTS	
Tea		Rice	
Coconut Products		Cotton Goods	
Rest		Coal & Coke	

FIG. 187.

EXERCISES

1. Name *three* of the chief exports of Ceylon. Describe the conditions necessary for the large-scale cultivation of *one* of them.
2. Draw a sketch-map to show why Colombo is such an important port. Name *three* other ports in the island.

THE PENINSULA OF INDO-CHINA AND MALAYA

The Peninsula of Indo-China, consisting politically of Burma, Siam, and Viet-Nam, Cambodia, and Laos, stretches south into Malaya. The following lines of fold mountains run from north to south across the peninsula: (i) the Arakan and Pegu Yoma in Western Burma; (ii) a central range, east of the Shan Plateau, and continuing south through the Malay Peninsula; and (iii) the mountains of Annam, fronting the China Sea. Between the ranges the Irrawaddy, the Salween, the Menam, and the Mekong flow in deep valleys which broaden out towards the sea. In the north-east of this region the Red River follows a south-easterly course to the Gulf of Tongking. With each recurring flood these long swift rivers, carrying enormous loads of sediment, deposit fresh alluvium in their valleys and over their huge deltas.

The *climate* of the greater part of Indo-China resembles that of India. There is a rainy season when the south-west monsoon blows from May to October, followed by a dry period which is most pronounced in December and January. But the eastward slopes of the Annamite mountains and the plains at their base receive rain in the cool season, for they lie in the track of the north-east monsoon blowing across the warm China Sea.

BURMA

Burma, about three times the size of Great Britain, has a population of 21 millions, the majority of whom belong to the Mongolian race. Most of the people are Buddhists and it would be difficult to find a town or village without its pagoda. Formerly part of the British Commonwealth, Burma became an independent republic in 1948. The country almost coincides with (i) the basin of the Irrawaddy; (ii) the western part of the Shan Plateau; (iii) the middle and lower Salween which crosses the latter area; (iv) the Sittang valley; and (v) the Tenasserim coast region.

Rice, the chief crop, is widely grown in the deltas and lower valleys of the Irrawaddy and Salween. In contrast with India, quantities are available for export, as far more is grown than is required by the population. Production has, however, declined somewhat in recent years. Much of Burma is forested. *Teak*, the most valuable tree, grows in single stands scattered amidst other less useful timber. When a tree is selected for felling, a ring is cut through the bark round its base, thus killing it. It is then left to dry for three years, for otherwise it would be too heavy to float. After the trees have been felled they are hauled to the streams by buffaloes or elephants, and when the *flood waters begin to rise the logs are floated down to the main rivers*, where they are fastened into rafts which travel down to Rangoon, in most cases a six months' journey distant.

Petroleum, found in the middle of the Irrawaddy valley, is refined at Rangoon; lead and silver are mined in the north of the Shan Plateau, tin and wolfram near Tavoy, on the Tenasserim coast. *Rangoon* (740,000), the port-capital, exports petroleum, rice, and teak, and manufactures imported cotton. From Rangoon a railway runs up the Sittang valley to *Mandalay*, on the Irrawaddy, the chief town of Upper Burma. From here a branch runs north-east to Lashio, and the main line continues north to Mitkyina, the rail-head.

THAILAND (SIAM)

Thailand, an independent kingdom lying between Burma and Indo-China and extending southward into the Malay Peninsula, has an area of 198,000 square miles. Its people, about equal in number of those of Burma, are also mainly of Mongolian stock. Rice is the chief crop, the staple food, and leading export. Teak, felled in the forests of Upper Thailand, is floated down the Mcnam to *Bangkok*, the capital and only large town, connected by rail with Singapore. Tin and wolfram are mined.

INDO-CHINA

Indo-China, one and a third times the size of France, has a population of 30 millions. Before the last war it consisted of a French colony (Cochin-China) and four protectorates. It now comprises three independent states, namely *Viet-Nam* (divided into a Northern and a Southern Zone) in the east; *Laos*, lying between the Annam Range and Thailand; and *Cambodia* in the south-west.

The mountains are forested, but the coastlands, and especially the deltas of the Mekong and the Red River, are richly cultivated. The Mekong receives the waters of Lake Tonlé Sap, which during the summer floods acts as a natural reservoir. The enormous delta of the river is aptly termed 'the gift of the Mekong', since it is one of the world's great rice-growing regions. Apart from rice, crops include maize, sugar-cane, and rubber. Some coal, tin, and zinc are mined. Fisheries are carried on in the rivers, lakes, and coastal waters.

Rice, dried and salt fish, and rubber are exported from *Saigon*, east of the Mekong delta, which has rice and saw-mills. *Hanoi*, the capital of Viet-Nam, stands on the Red River, some distance above *Haiphong*, a port exporting coal.

MALAYA

In the Malay Peninsula lowlands of varying width border the mountainous granite backbone, which is 8,000 feet above sea-level. On the west there is a gradual slope to the mangrove-fringed shores of the Strait of Malacca, but the east coast is bolder, consisting of promontories interspersed with bright sandy beaches.

The peninsula lies in the equatorial wet belt between the Asiatic

23. TEAK AND RICE

(Above) Elephants moving teak in Burma. Logs are floated down the rivers from the forests of Upper Burma, where the teak trees grow in single stands (Below) Young rice plants being transplanted. The land must be kept irrigated until the leaves turn yellow and the rice begins

24. TERRACED CULTURE—A VILLAGE IN THAILAND

(Above) Terraced hill-sides in Java where the crops grown vary with the elevation (see p. 302).
 In the Thai village (below) the houses are built on platforms so as to be secure against the floods (see p. 296).

and Australian monsoon areas. The seasons depend not on temperatures, which are uniformly high, but on rainfall. At Singapore, in

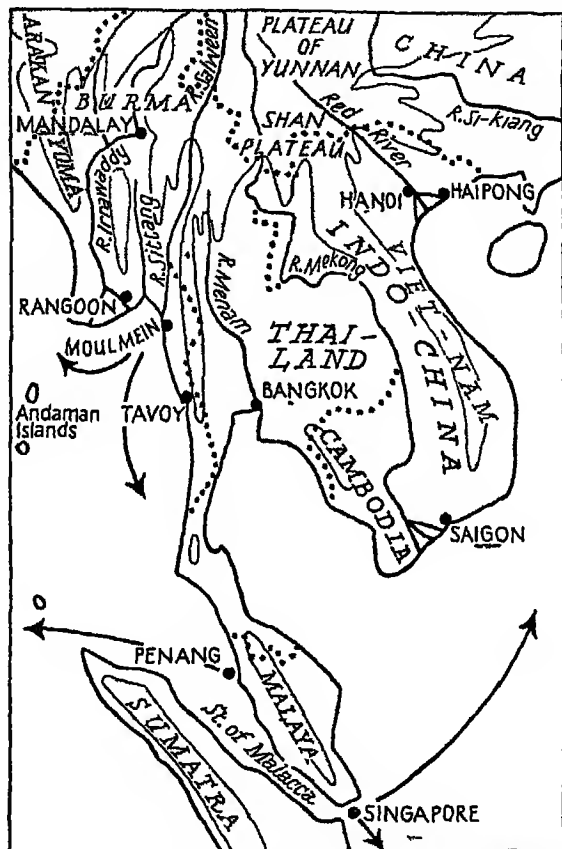

FIG. 188. The Peninsula of Indo-China and Malaya.

the extreme south and almost on the equator, every month is wet, but farther north there is, as in India, a wet season from May to October, followed by a relatively dry season. Apart from areas cleared for cultivation or mining, the whole region is thickly forested with an immense variety of trees.

The south of Malaya is part of the Commonwealth. It consists of (a) the *State of Singapore*, an island off the south of the Malay Peninsula, and (b) the *Federation of Malaya*, comprising the eleven Malay States, each having its own ruler. In 1963, Malaya and Singapore united with North Borneo, Sarawak, and Brunei to form the *Federation of Malaysia*. The total area of Malaya is about 50,000 square miles and the population is $7\frac{1}{2}$ millions. Owing to (i) its mineral wealth; (ii) its uniformly high temperatures and heavy rainfall, which are admirable for rubber and other tropical products; and (iii) its accessibility compared with other equatorial forest areas, Malaya is by far the most important part of the Indo-China-Malay Peninsula.

The bulk of the world's natural *rubber* is obtained from plantations in South-East Asia, where Malaya and Indonesia are the chief producing areas. Some is also obtained from Ceylon. In Malaya most of the plantations are situated on low hill-sides where the deep soil is well drained to prevent the heavy rainfall clogging the roots of the trees, which are tapped from the fifth year onwards. The latex obtained from them is treated at the plantation factory with acetic acid, which causes it to form a junket-like mass of pure white rubber floating in a clear whey. This process is known as coagulation. The coagulated rubber is passed through the rolling machines, from which it emerges in thin sheets which, after they have been smoke-dried, form the smoked sheets of commerce. Another process produces *crêpe* rubber.

Coconut palms are found throughout Malaya. The chief plantations are on the flat coastal lowlands of the south-west, from which area most of the copra that is exported is obtained. Though much rice is cultivated yet much is also imported to cope with the demand. Most of the British supply of pineapples comes from Malaya. Other crops include sugar, pepper, oil-palms, tapioca, nutmegs, sago, and tobacco.

Malaya supplies more than a third of the world's *tin*, most of which is found under the alluvial deposits of the lowlands. Much is obtained by dredging. The leading tin-mining districts are those round Ipoh and Kuala Lumpur. A considerable proportion of the ore is smelted at Singapore and Penang prior to export. Some coal is also mined.

Singapore stands on an island at the southern extremity of the

Malay Peninsula. Placed at the converging point of trade routes between India and China, and Japan and Australia, it is one of the chief seaports in the Far East, and a major airport on the route from London, via Karachi, to Sydney, Australia. Singapore is also a great entrepôt port collecting and exporting rubber, tin, and copra from Malaya, and spices and other products of the East Indies. *Penang*, the second port, also on an island, exports tin and rubber. *Kuala Lumpur* the capital of the Federation of Malaya, is joined by road and rail to Port Swettenham, on one of the finest harbours in Malaya.

Besides Malays, a people of mixed but mainly Mongolian origin, the inhabitants of Malaya include Chinese, Tamils from Southern India, and Pakistanis.

The Chinese are the chief traders and merchants, while many Tamils are employed on the rubber plantations.

FIG. 189. Site of Singapore.

EXERCISES

1. Write an account of the natural vegetation of the Peninsula of Indo-China and show how it is related to the climatic conditions. Name the chief vegetable products of this region.
2. What geographical conditions are favourable for the large-scale production of rubber? Describe briefly the processes by which it is obtained and prepared for export. Name the two most important producing areas in the world.
3. Draw sketch-maps to show the position of (a) Singapore and (b) Rangoon. In each case give some account of the trade of these ports.
4. Show how geographical conditions have influenced the industries of Burma.

THE EAST INDIES

The East Indies, lying between the mainland of Asia and Australia, extend from west to east for more than 3,000 miles, or a somewhat greater distance than that from Southampton to New York.

The fold-ranges, running from Sumatra, through Java and the Moluccas, to the Philippines contain along their weakened crests many active and extinct volcanoes. The islands have a present and potential importance as an accessible store-house capable of yielding immense quantities of tropical products.

The climate and products resemble those of the Malay Peninsula. Rain falls throughout the year. It is heaviest and most evenly

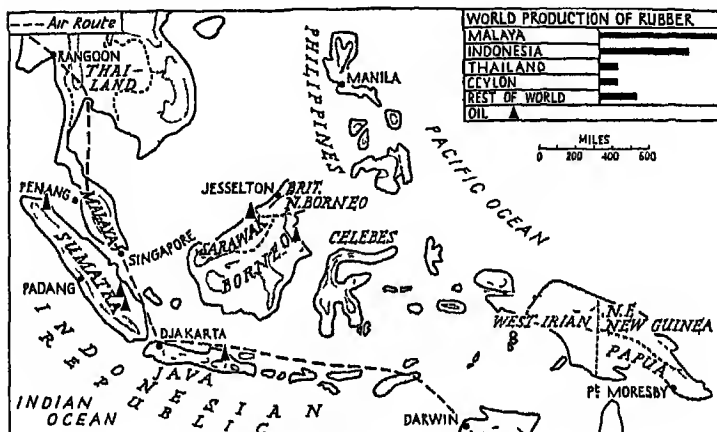

FIG. 190. Malaya and the East Indies.

distributed near the Equator, while islands farther north or south tend to have wet and dry seasons. All are thickly forested except where land has been cleared for cultivation, or where open woodlands occur at high elevations or in islands with marked dry seasons.

Communications have always been relatively easy. Owing to the successive waves of immigrants that have spread over the islands their peoples are of very mixed racial origin. The Malays, who form the bulk of the population, settled on the lowlands, driving more primitive folk living there into the inaccessible forested interiors, where their descendants—some still head-hunters and tree-dwellers—are still to be found. Portuguese and Spanish conquerors were followed by the Dutch and, later, by the British. In 1899 the United States took the Philippines from Spain, but in 1946 the islands were granted independence and became a republic.

The *Republic of the Philippines*, consisting of some 7,000 islands and islets of which the chief are *Luzon* and *Mindanao*, has an area of 115,000 square miles, and a population of some 19 million. The extensive forests yield ebony, dyewoods, gums, and cedar. From the coco-nut plantations along the coastlands copra and coco-nut oil are obtained. The islands rank amongst the foremost countries in the world for coco-nuts and coco-nut products. Manila hemp (abaca), sugar-cane, and tobacco are also among the leading exports. Rice is cultivated, but much is also imported. *Manila* (1,000,000), the capital, on *Luzon*, has a splendid natural harbour, which affords protection from the typhoons which are frequent in the surrounding seas. It is a centre for air travel in the Far East.

Borneo, a densely forested island, with an area of 284,000 square miles, is divided into two roughly equal portions by the equator. The north, which forms part of the Federation of Malaysia, consists of *North Borneo* (with the small island of *Labuan*), and *Sarawak*, and *Brunei*. Products include rice, rubber, and copra. There are oil wells in *Brunei*. *Jesséltón*, capital of *North Borneo*, is linked by air with *Singapore*, *Manila*, *Hong Kong*, and *Darwin* (*Australia*).

The rest of *Borneo* forms part of the *Republic of Indonesia*. This country comprises all the former Dutch territories in the East Indies including *Java*, *Sumatra*, the *Celebes*, the *Moluccas*, the west of *Timor*, and *West Irian* (west *New Guinea*).

Coffee and cacao are grown in the *Celebes*; nutmegs and cloves come from the *Moluccas*, or *Spice Islands*. *Sumatra*, the second largest island in the archipelago, is still only partly developed. Rubber, tea, coco-nuts, and tobacco are cultivated; the mineral wealth includes petroleum found in the north and south, and coal, which is exported from *Padang*, on the west coast. The development of the east coast is hindered by mangrove swamps. There are rich deposits of tin in the neighbouring islands of *Banka* and *Billiton*.

Of all the islands *Java* is by far the most developed. Together with the adjacent island of *Madura*, it has 58 million inhabitants. Its remarkable development is due in part to its rich volcanic soil, its climate, and the absence of mangrove swamps. The original Malay stock was improved by intermingling with Hindu settlers, with the result that the modern Javanese are more industrious than the less mixed Malay type.

A wonderfully intensive system of agriculture is carried on. The

hill-sides are terraced up to 5,000 feet thus allowing the heavy tropical rains to sink into the land, instead of wearing it away and causing disastrous soil erosion. There are coco-nut and cacao plantations along the coast, and though rice is cultivated everywhere in the lowlands much has to be imported. Rubber, with pineapples planted between young trees, is grown on the foot-hills, and sugar-cane, tea, coffee, tobacco, and maize at succeeding elevations. Then come cinchona trees and open grazing lands, where humped cattle are bred. Outside the volcanic soil areas forests abound: the most important tree is teak. Minerals include petroleum, tin, and coal. *Djakarta* (Batavia), the capital of Indonesia, lies in the north-west of Java, near Sunda Strait. The chief exports of the republic are rubber, petroleum, tea, copra, tin, and pepper.

FORMOSA (TAIWAN)

In 1895 Formosa was taken from China by Japan, under whose rule it remained until the end of the Second World War. A rugged forested island, about the size of Great Britain, it lies athwart the Tropic of Cancer and has a tropical monsoon climate. There are heavy summer rains, but the winters are not dry and frosts are unknown in the lowlands. It is one of the chief sources of the world's supply of camphor, which is distilled from the leaves and twigs of an evergreen tree resembling a laurel. Much tea is grown.

EXERCISES

1. Draw a large sketch-map to show the relative positions of *three* of the most important East Indian Islands. Account for the density of population on *one* of these islands.
2. Among the chief crops grown in Java are cinchona, coffee, coco-nuts, maize, pineapples, rice, rubber, sugar-cane, and tea. (a) Starting with the crop grown at the lowest elevation, arrange the others (named above) in order according to the altitude at which they are cultivated. (b) Name *three* of the crops which you think are grown mainly for export. (c) Name *one* crop produced chiefly for home consumption. (d) In the case of *one* crop only describe briefly the climatic and other conditions necessary for its successful cultivation.
3. Summarize, in tabular form, the geography of Malaya under the following heads: *Relief, Climate, Natural Vegetation and Crops, Minerals, Towns.*
4. Write a short geographical account of the Philippine Republic.

CHINA

China, a Communist Republic, has an area of over 4 million square miles. Besides China Proper, it includes Manchuria, Inner Mongolia, Tibet, and Sin-kiang. Its total population (nearly one-quarter of the human race) exceeds 716 million, and is growing at the rate of roughly one million a *month*. With so many mouths to feed, it is not surprising that food production is one of the Government's most critical problems, and to increase the output agricultural methods have been revolutionized. At the same time such great advances have been made in industry that China is rapidly becoming a leading industrial power.

China Proper. Outside the great alluvial plains drained by the Hwang-ho and the Yangtze-kiang, most of China is mountainous. On the west lofty mountains and plateaux hinder communication with Burma and Tibet. In the north-west, where natural boundaries are not so well defined, the Chinese built their Great Wall, completed two centuries B.C. to protect their country from invaders from the Mongolian steppes.

Most of China lies north of the Tropic of Cancer, whereas much of India lies to the south. This fact, coupled with the absence of a protecting mountain barrier on the north, accounts for the cold winters experienced in Northern China. As the country has a monsoon climate rain falls mainly in summer. It is heaviest in the south, where no month is quite rainless.

Owing to the large amount of mountainous land, all suitable ground is intensively cultivated, and densely peopled by millions of workers, the bulk of whom live in walled towns and villages. In the lowlands the natural vegetation has almost disappeared. Little land is available for pasture, and few animals—apart from draught buffaloes, pigs, and poultry—are reared. Over 80 per cent. of the Chinese depend on agriculture for their livelihood. For centuries each peasant family had its own plot of land on which to grow food for its needs. Now, under the Communist Government, the land is divided up into farms, called *co-operatives*, some covering 50,000 acres and being worked by as many as 1,500 families. On such farms (unlike the collective farms of Russia) little machinery is used, for the simple reason that if it were far fewer workers would

be needed, and there would soon be mass unemployment. The land is irrigated by countless canals. Water is often lifted by water-wheels driven by buffaloes or turned by treadmills worked by man-power. In mountainous districts water is sometimes raised from one canal to another, to a height of several thousand feet. Silt

FIG. 191. China.

from the waterways, as well as all other available material, is used to fertilize the land, from which the industrious Chinese wrest, with difficulty, a livelihood. Rice is the staple food crop in Central and Southern China, and millet and soya beans in the drier, cooler north. Cotton and tea are widely grown, and in the south mulberry trees (for silkworms).

China may be divided into—(1) Southern China, centring on the Si-kiang; (2) Central China and the Yangtze-kiang Basin; and (3) Northern China, including the plain drained by the Hwang-ho, and the hilly Shantung Peninsula.

25. IRRIGATION—A RUBBER PLANTATION

(Above) These giant water-wheels lift water from the Hwang-ho for irrigation, but they operate only at high water seasons. (Below) In this rubber plantation in Malaya the coolie has just made a thin incision in the bark of the tree, and the latex, which is running down into the cup beneath, will soon be emptied into the pail. Note the "contour" planting on the hillside in the background.

26. CANTON AND TOKYO

(Above) Canton, the chief port of Southern China. Many of the people live in sampans on the river. (Below) Part of the business quarter of Tokyo, the capital of Japan, and the world's largest city.

Southern China. Southern China is a mountainous region rising to the bleak Tibetan Highlands through the limestone plateau of Yunnan, rich in tin and other minerals. Much of this rocky and rugged hill-country is clad with forests yielding good hard timbers, camphor, wax, and innumerable bamboos. On the east, the mountains border a sunken coast indented by many rias, which form splendid harbours, like that on which stands *Amoy* (234,000), the chief port of Fukien, a famous tea-growing province. But most of the rugged forested interior is unsuited to cultivation, and the people

FIG. 192. Site of Hong Kong.

in maritime districts have turned to the sea for their livelihood. Many are fishermen or sea-traders, others are pirates. Some have gone further afield and have settled on islands in the Pacific, in the East Indies, or in the Malay Peninsula, where they work as traders, in mines, or on plantations.

But the hot rainy summers, and relatively mild winters when some rain falls, favour the growth of sub-tropical products, and on the alluvial soils in river valleys, like that of the Si-kiang, much intense cultivation is carried on. Rice, sugar-cane, and cotton are cultivated on the lowlands, tea on the hill-sides. Other crops include oil-seeds and indigo, and mulberry trees associated with sericulture.

The Si-kiang is navigable for nearly 1,000 miles. Canton (1,500,000), the chief town of Southern China, some 90 miles from the sea, stands on the Canton river at the head of the delta built up by the Si-kiang, Pei-kiang, and the Tung-kiang. It manufactures silk, cotton, and woollen goods. South of the Canton river is the Portuguese island of *Macao*,

The British island of *Hong Kong* lies at the mouth of the Si-kiang river. The territory of the Colony includes part of the mainland opposite. *Hong Kong* (Victoria) is an important naval station and entrepôt port for Southern China. Its imports include flour, coal, and rice, and its main exports (including re-exports from China) are tea, silk, and cotton. In addition to shipyards, it has factories engaged in rope-making and tobacco manufacture. Tin from Southern China is smelted here, and cement is manufactured.

Central China and the Yangtze-kiang Basin. From its source in the Kunlun Mountains to its mouths in the East China Sea, the Yangtze-kiang measures over 3,000 miles. Its basin, which forms Central China, comprises about one-third of the country containing, within its 700,000 square miles, more than one-third of its entire population. In its upper course the Yangtze is little used for transport, but throughout its middle and lower course it is navigable. Together with its tributaries, and a remarkable network of canals used for irrigation, transport, and drainage, it is the main highway and source of life for the 150 million Chinese living in its basin, or whose homes are junks floating on its waters.

In the Yangtze basin the winters, though cold, are not so extreme or dry as those of Northern China, while the hot rainy summers favour the growth of rice, tea, and cotton.

In its course through China proper the Yangtze may be divided into four sections: the Red Basin of Szechwan; the Ichang Gorge; the Middle Basin; and the Lower Basin and Delta.

The Red Basin is more than double the size of the British Isles. It has hot summers, but owing to the encircling mountains its winters are milder than most parts of Central China, and frosts and snows are rare. The Kialing, the Min-ho, and other snow-fed streams rising in Tibet are used to irrigate the rich alluvial red soil. Rice is grown on wet lowlands, and wheat, millet, beans, opium, sugar, tobacco, and tea on plains and hill-sides terraced up to several thousand feet. Coal, iron, and copper are mined. Of many walled cities and towns the chief are *Chengtu*, the capital of Szechwan, and *Chungking* (1,600,000), the principal port, at the confluence of the Yangtze and the Kialing.

The Yangtze is bordered by hilly country from Chungking as far as *Wanhsien* (300,000), at the entrance to the Ichang Gorges, where

the pent-in waters form a series of dangerous rapids extending for 160 miles as far as Ichang.

Below Ichang the river is navigable to the sea, a distance of some 900 miles. From Ichang to Hankow the Yangtze flows through the *Middle Basin*, where it receives a number of tributaries, including the Han from the north-west, and from the south-west the Siang-kiang which carries the drainage of Lake Tungting. In spring huge timber rafts are floated down the latter river, portions being sold at towns *en route*. Every available portion of the alluvial lands of the Middle Basin is intensively cultivated, and the whole country-side looks rather like an unending series of allotment gardens dotted with clusters of huts built of reeds, with here and there walled villages.

The Han enters the Yangtze at the point where the latter river enters its *Lower Basin*. Here stands the triple city of *Hankow-Hanyang-Wuchang*. Together the three places, known as *Wuhan*, have a total population of rather more than 1½ million. Though it is 600 miles from the sea, Hankow is a port for ocean-going steamers. Standing on the north-to-south railway from Peking to Canton, it is a great tea market and has cotton, hemp, and flour mills. Hanyang, on the opposite bank of the Yangtze, is noted for its iron and steel works, which are fed with coal and iron from the *Hunan field* to the south. *Nanking* (1,000,000), stands farther down-stream. It is a busy industrial city with cotton, silk, and other textile factories, and paper mills. *Shanghai* is the outlet for the Yangtze valley. The population of Greater Shanghai, including its sprawling industrial and residential suburbs, exceeds 6 million, and it ranks as the fourth largest city in the world being surpassed only in size by Tokyo, London, and New York. It is situated on the Whangpoo River, on which its outport of Wusung stands at the point where the Whangpoo enters the Yangtze estuary. The chief entrepôt port in China, Shanghai exports tea, cotton, and silk, while its manufactures include silk, woollen, and cotton goods.

Northern China. Northern China consists of the basin of the Middle and Lower Hwang-ho, the lesser area to the north drained by the Pei Ho, and the Shantung Peninsula to the north-east. We may divide Northern China into (a) the mountainous and upland area in the west, (b) the lowland plain to the east, and (c) the hilly Shantung Peninsula. Much of this region is covered with *loess*, a

yellow soil composed of dust brought by the prevailing winds from Mongolia. Though porous, it is extremely fertile and needs only water to make it bear wonderful crops.

So great an amount of sandy yellow sediment is carried seawards by the Hwang-ho that its very name is derived from the colour of its muddy waters (Hwang-ho = Yellow River), as too is that of the Yellow Sea, into which it formerly poured its silt-laden load. In its lower course the Hwang-ho, flowing slowly over the plain, deposits much sediment on its bed, which, like that of the lower Mississippi, is being continually raised. On occasions the embankments that have been built to keep the stream within bounds burst, and thousands of square miles are flooded, with disastrous loss of life and incalculable material damage. After the waters subside the river may return to its bed, but sometimes it seeks a fresh outlet to the sea. During the last 2,500 years it has changed its course at least eleven times. It now flows into the sea to the north of the Shantung Peninsula, but in 1851 its mouth was to the south. On the middle Hwang-ho a huge dam is now being built across the Sanmen Gorge to provide water for irrigation and hydro-electric power.

In Northern China the winters are dry and cold, and strong dust-laden monsoon winds from the north-west blow almost continuously. The bleak and severe conditions have done much to make the northern Chinese a hardier folk than those living in the south. The summers are hot but the rainfall is less than in the rest of China, and in those years when it is insufficient droughts and famines occur. Rice can be grown on the lowlands as far north as the Pei-ho, but the chief crops are of a hardier variety such as millet, wheat, barley, and soya beans. Cotton is cultivated in the Shantung Peninsula. From Lanchow, on the middle Hwang-ho, a newly constructed railway to Hami is being continued to Urumchi, the capital of Sinkiang.

In the *Shansi Highlands*, marking the western edge of the Northern Plain, anthracite and iron ore are mined.

From *Peking* (2,900,000), the capital of China, railways run (1) north-east to Shenyang (Moukden); (2) south to Tientsin and Nanking; (3) south via Wuhan to Canton; and (4) north-west to Kalgan, and across Mongolia via Ulan-Bator to Ulan Ude, on the Trans-Siberian Railway. The chief port of Northern China is *Tientsin* (2,700,000), on the Pei Ho, whose outport is Taku.

Manchuria. Manchuria may be compared to a lipped bowl, of which the lip reaches the Yellow Sea on the south and whose rim is formed by the surrounding mountains. Like Northern China, it has fairly rainy summers though the winters are colder. Much of

FIG. 193. Manchuria

Manchuria is a steppe country, but the north and east are forested, and in spring timber rafts are floated down the Sungari to saw-mills at Harbin, and down the Yalu to mills at Antung at the mouth of the river. Much wheat is grown. But even more important are millet, and soya beans which are ground into flour and pressed for their oil, the residue being made into cattle-cake. Soya beans, bean-oil, and cattle-cake are among the chief exports of *Dairen*, which, with the adjoining town of *Port Arthur*, has a population of over a million.

To-day, Southern Manchuria is one of the foremost industrial areas in China. The chief industrial centres lie on, or near, the railway running north from Port Arthur. At *Anshan* huge iron and steel works draw iron ore from mines near by, and coal from the

Fushun coal-field—one of the most important in China—where coal is dug by mechanical shovels from open mines. At *Shenyang* (Moukden), a city with 1,300,000 inhabitants, there are flour and bean-oil mills, and factories that make turbines and transformers, and turn out enough machine tools to supply most of China's needs. Lorries and aircraft are built at *Changchun* (Hsinking), whose factories are powered with electricity from a hydro-electric power station on the upper Sungari River.

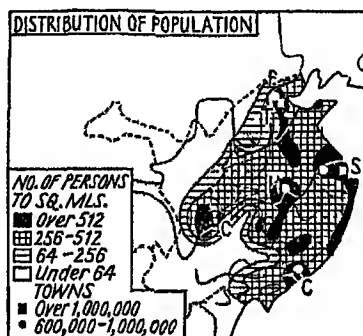

FIG. 194.

From Changchun the railway runs on to *Harbin*, a junction for the Trans-Siberian Railway, which here crosses the Sungari. Its position at a meeting-place of rail and water routes has helped to make Harbin a great trading centre; and, with a population of 700,000, it is the third largest city in Manchuria.

Transport and Trade. Lack of good transport facilities for long retarded the development of China, but today industrial expansion is being matched by road and rail construction though the mileage is still quite inadequate. At present there are about 110,000 miles of roads more or less suitable for motor traffic. They include one road going to Burma, another connecting China with Indo-China, and two running to Tibet. But most of the roads are still mere earth tracks, often too narrow for vehicular traffic. In the north one-wheeled wagons and carts drawn by donkeys, oxen, horses, and mules are used, but in the main—especially in the south—land transport is still carried on by means of pack animals and by coolies.

A great internal trade is carried on over the country roads, and by canals and rivers whose mileage exceeds that of any other country.

Among the new railways that have been built recently is the line from Peking across Mongolia to Ulan Ude (U.S.S.R.). This line shortens the distance between Peking and Moscow by 600 miles compared with the old Trans-Siberian route via Harbin. Lines now under construction include one from Lanchow, on the middle Hwangho, going eastward to Sinkiang.

There are internal air services between the largest cities, but most people cannot afford to travel by air. At present the only external air service is a weekly one linking Peking with Moscow and Prague.

FOREIGN TRADE OF CHINA			
EXPORTS		IMPORTS	
Animal Products		Metals & Ores	
Oils Tallow & Wax		Machinery	
Metals & Minerals		Chemicals	
Seeds		Dyes & Paints	
Hides & Skins		Raw Cotton	
Tea		Wool & Woollen Goods	

FIG. 195.

Owing partly to the low standard of living, and partly to her great and varied resources, China needs relatively little from the outside world. The foreign trade per head is small, but owing to the enormous population the total amount is considerable. About 75 per cent. of the foreign trade is carried on with Soviet Russia and other communist countries. Exports include animal products, metals and minerals, silk and tea. Among the imports are machinery, chemicals, metals, and raw cotton to supplement home supplies.

KOREA

The mountainous and forested peninsula of Korea was a dependency of Japan from 1910 until the end of the last war, when it was divided into a Soviet occupation-zone to the north of the 38th parallel, with an American zone to the south. Subsequently each zone became a Republic. Of the 30 million people who live in Korea, about three-quarters have their homes in the south. Rice,

beans, millet, and tobacco are grown on lowlands fronting the Yellow Sea. Iron and coal are mined in the mountainous north, where hydro-electric power and some heavy industries were developed by the Japanese. From *Pusan*, a port for Japan, a railway runs through *Seoul* and *Pyongyang* to *Moukden* (Manchuria).

EXERCISES

1. (a) Draw a sketch-map of the Yangtze-kiang Basin. On your map shade the high land so as to bring out clearly the *three* chief areas into which the basin may be divided. Mark and name *three* important tributaries and *five* of the principal towns. Indicate the main areas of production of the chief crops and minerals. (b) Describe the geography of the basin under the following headings: Relief, Climate, Occupations, and Products. (c) Write short notes on *three* of the chief towns in the basin (excluding the seaport which is its outlet).
2. Describe a railway journey from Canton to Peking, paying attention to the different types of country through which you would pass.
3. Write an account of the chief modes of transport in China and so far as you can relate them to the geographical conditions.
4. What is an entrepôt port? Illustrate your answer by sketch-maps, and describe the position of two of the chief entrepôt ports in or off the coasts of China. Give some account of their trade and show how their growth has been influenced by their situation.
5. Compare and contrast the climate and products of Southern and Northern China.
6. Name two centres of heavy industry in China and account for their location. Illustrate your answer by sketch-maps.
7. Draw a map of Manchuria and on it shade the high land, insert two of the chief rivers, print forests over two appropriate areas and the names of *two* important crops each over *one* area noted for their cultivation. Insert and name the capital and *three* other towns, and show *one* important railway.
8. Describe the distribution of population in China and account as fully as you can for the facts you state.
9. What areas would you include in the 'monsoon lands' of Asia? Give reasons for the limits you adopt for the whole tract, and state shortly the geographical conditions that have been favourable to the growth of the population which numbers half mankind.
10. Indicate, by sketch-maps, the position of Canton, Nanking, Peking, and Hankow. In the case of *two* of these towns, show how their growth has been influenced by their geographical position.

JAPAN

The Rise of Japan. Three-quarters of a century ago Japan was a little-known country whose people lived in a feudal state resembling that of Britain in the Middle Ages. But the year 1854, when the United States persuaded Japan to open her ports to foreign trade, marked the beginning of a new era. The Japanese began to adopt Western ideas ; in 1871 the old feudal system was abolished and a new Japan arose. Advances in the scientific and industrial fields were accompanied by military, naval, and maritime expansion which resulted in territorial acquisitions at the expense of China and Russia. In 1895 the former country ceded Taiwan (Formosa) to Japan, and in 1905, after the Russo-Japanese War, the southern part of the Liaotung Peninsula, together with Port Arthur, passed under her rule. After the First World War Japan was given a mandate over the Marianne, Caroline, and Marshall Islands in the Pacific, which formerly belonged to Germany. In 1932 she obtained control of Manchuria, where she established a dependent state, known as Manchukuo. In 1937 Japan began to overrun China. In December 1941 she entered the Second World War as an ally of Germany. After her defeat in that conflict Japan lost all her overseas possessions.

The temperate climate of Japan has helped to make the people a hard-working race. The Japanese are skilled farmers and clever craftsmen. They have the reputation of being imitators rather than original thinkers. Their industrial development was due largely to the way they adopted, and adapted, the methods of more advanced industrial nations. In Japan today there are too many people and too little space. And the Japanese can only provide food and work for their ever-increasing population by expanding their industries and increasing their exports.

The Japanese Islands. Japan consists of about a thousand small and four large islands which form the nucleus of the country : *Hokkaido*, the most northerly, is a little smaller than Ireland ; *Honshu*, or *Mainland*, is approximately equal in area to Great Britain ; *Shikoku*, lying south of the Inland Sea, is about as large as Wales, and *Kyushu* is almost half the size of Ireland. Japan has an area of 141,529 square miles and a population of over 95 millions.

All the islands consist of a mountainous interior surrounded by narrow disconnected lowlands usually crossed by swift short streams, of little use for navigation but valuable as sources of potential and

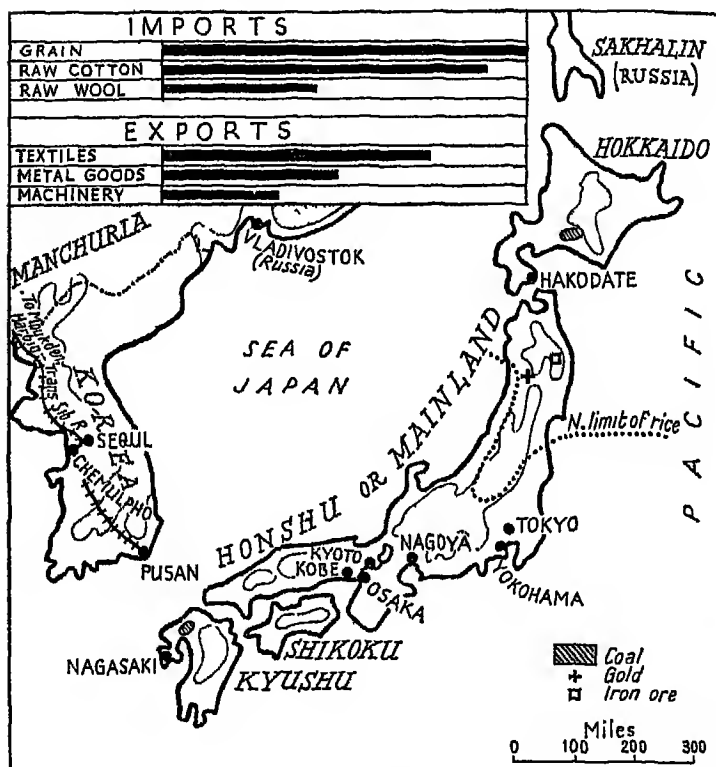

FIG. 196. Japan.

developed hydro-electric power. Of numerous volcanic peaks about fifty are still active. Earthquakes are common, and though the majority are extremely slight some are most destructive, such as that which occurred in 1923, when much of Tokyo and the whole of Yokohama were destroyed. The many excellent harbours around the coasts have played no small part in making the people a sea-

far-*ing* race. Much fishing is carried on. Japan has a large merchant fleet. She is a major shipbuilding nation, and ships are among her leading exports.

Climate, Vegetation, and Crops. Japan has a temperate monsoon climate modified by its insular position, which makes it less extreme than corresponding areas in China. The mountainous interior of the islands and the presence of ocean currents cause climatic differences between west and east. In summer the south-east monsoon winds bring rain to the greater part of Japan, but especially to the south and east. Most rain falls during the latter part of June and early July, when it is beneficial to the newly planted rice crop. In winter the prevailing wind blows from the north-west. At this season the west of Honshu receives considerable rain, but the east coast lands, now on the leeward side of the mountains, have little rain, for the winds (*a*) have lost most of their moisture, and (*b*) blow off-shore in this region. The warm Kuro Siwo current washes the south-east coasts of Japan: the cold Kurile current flows along the east coast of Hokkaido and that of Honshu almost as far south as Yokohama. In the area where the two meet there are frequent fogs owing to the mingling of the cold and warm air. In summer the air over the Kuro Siwo is relatively cool, compared with that over the land, and thus this current has a slight cooling effect along the east coast. In winter, however, when it might be expected to raise the temperature, the off-shore north-west winds minimize its moderating effect. The cold Kurile current helps to reduce the temperatures along the east coast (north of Yokohama) at all seasons. The prevailing north-west winter winds from Siberia also cause the winters in Hokkaido to be very severe. In Japan changes of season are accompanied by violent typhoons which are most dangerous to shipping.

Owing to the range of latitude there are considerable differences in temperature between north and south. In Hokkaido the winters are severe, the summers warm. In Honshu the winters are cold, and severe in the mountains, while the summers are hot, especially in the south. Shikoku and Kyushu have a sub-tropical climate.

Some 60 per cent. of Japan is forest clad, and partly because of this and partly on account of the mountainous nature of the country 16 per cent. only is suitable for cultivation. Deciduous forests, with poplar and aspen trees, and conifers at higher elevations, are found

in the north. In the south are sub-tropical forests with camphor, mulberry, and lacquer trees, as well as innumerable bamboos.

¶Rice, the staple crop, is extensively grown in the south. Planted in June it is harvested in September before the torrential rains which mark the end of the monsoon. Wheat and barley, sown in autumn often on the same land as rice, are ready for cutting in May. Millet, soya beans, and potatoes are widely grown. Meat, milk, and tinned foods now supplement the traditional diet of rice, soya beans, and fish. About 750,000 acres are planted with mulberry trees for sericulture, for which the warm climate, coupled with the cheap labour provided by the women and children of the farmers' families, makes Japan well suited to silk-production, but output is less than formerly. Tea is grown on terraced hill-sides in the south of Japan. Other crops are tobacco and pyrethrum.

The land is tilled by peasant farmers, whose average holdings are only $2\frac{1}{2}$ acres in area. With a population of over 95 million, increasing at the rate of a million a year, and with so small a proportion of productive land, every available tract is cultivated. The land is tilled with great care, and by hard work, the use of fertilizers, irrigation, and terracing, the farmers raise large crops. Mechanization is increasing: much use is made of low horse-power machines, such as power tillers which resemble small tractors, and small motor threshing machines. ¶Owing to the necessity for using the land for crops, and to lack of suitable pasture, animal farming is relatively undeveloped, though recently the number of cattle has increased, and milk output has risen. There is, for example, a thriving dairy industry in Hokkaido.

Minerals, Manufactures, Towns, and Trade. Among the minerals mined in Japan proper are *copper*, *zinc*, and *silver*. The chief *coal-fields* are in the north-west of *Kyushu* and in the south of *Hokkaido*, but there is little top-grade coking coal and much is imported. Iron ore is mined in the north of Honshu, but the supply is unequal to the demand, and much is imported. Japan is one of the leading steel-producing countries. She ranks after the United States and Canada in her developed hydro-electric power: over 80 per cent. of her electrical energy is derived from this source. Besides a large number of big modern factories, there are many small concerns employing only a few workers. Among

the chief industries are those engaged in shipbuilding, and in the manufacture of chemicals, machinery and metal goods; textiles, notably cotton, woollen, silk, and rayon goods; and glass and pottery. All the chief cities are situated on Honshu. *Tokyo* (10,000,000), the capital, and now the world's largest city, is the chief commercial centre of the country. Both the modern steel-framed buildings used for industrial purposes, and private dwellings, most of which are built of light wood, are constructed so as to resist earthquakes. *Yokohama* (1,460,000), the port of Tokyo, imports raw cotton, sugar, flour, and soya beans, and manufactures silk and rayon. *Nagoya* (1,655,000), west of Yokohama, makes cotton goods, glass, and pottery, and imports raw cotton, rice, coal, and sugar. The town is also a centre of the woollen industry of Japan. Both *Osaka* (3,140,000) and the neighbouring port of *Kobe* (1,000,000) manufacture textiles and chemicals, and build ships. *Kyoto* (1,150,000), a short distance inland, the former capital, is a tea market and centre for the manufacture of silk, pottery, porcelain, and lacquer goods. *Sapporo* (525,000) is the capital of Hokkaido.

The north-west coastal belt of Kyushu is noted for heavy industry. Local coal is fed to iron and steel works at *Yawata* and other ports, and to cement and glass works. *Nagasaki*, south of the coal-field, builds ships.

Owing to the large and rapidly increasing population, the Japanese are unable to grow sufficient food or obtain, within Japan itself, enough raw materials for their manufactures. The policy of Japan, which ultimately led to her participation in the Second World War, was to acquire control of overseas territories which would yield food, raw materials, and markets for manufactured goods. Since the war Japanese industry and trade have shown a remarkable recovery. Like Britain, Japan depends mainly on imported raw materials for her manufactures. Unlike Britain, however, she has no vast supplies of high-grade coal. On the other hand, she has greater water-power resources.

Japan's chief imports are raw cotton from India, the United States, and Egypt; petroleum, iron ore; wool from Australia; rubber from Indonesia; and machinery from the United States and the United Kingdom. Of the foodstuffs needed to supplement home supplies, she imports rice from Burma, Thailand, and Indo-China; wheat from Canada; and sugar from Formosa, the Philippines, and

Indonesia. Her principal *exports* are cotton, rayon, and silk fabrics; electrical and other machinery; iron and steel goods and ships; and a variety of products including radio, television, and transistor sets, computing machines and cameras; porcelain, pottery, glass, and toys; and canned fish and fish products.

The United States provides the biggest market for Japan's silk products, and also for her transistor sets. Japan carries on more trade with the United States than with any other country. She also does a considerable trade with Australia, Canada, West Germany, and the United Kingdom; and with Asiatic countries, such as the Philippines, India, Pakistan, and Indonesia, which provide a large market for her cheap cotton and rayon goods.

EXERCISES

1. What type of climate has Japan? Compare the climatic conditions in the west of Honshu with those in the east of that island and account for the differences.
2. Give an account of Japan under the following headings: (i) Commercial importance of its position; (ii) Chief occupations other than manufacturing; (iii) Manufacturing industries with chief areas of production, and the geographical factors favouring their development.
3. Select *three* of the chief ports and *one* important inland town in Japan, and in the case of each show how geographical conditions have helped to make it important. Illustrate your answer by sketch-maps.
4. How do you account for the frequent earthquakes in Japan? In what kind of physical areas do you expect earthquakes to occur? Name *three* other areas—each in a different continent—subject to these phenomena.

CHAPTER XIX

THE ASIATIC MEDITERRANEAN LANDS

THE chief Asiatic Mediterranean countries are Turkey, Syria, Lebanon, and Israel. The typical Mediterranean climate is chiefly confined to the coastal areas, but generally speaking throughout this region the summers are hot, dry, and sunny, while nearly everywhere some winter rain falls, the amount diminishing with increasing distance from the Mediterranean.

Vast stretches consist of arid lands where sheep, goats, camels, and horses are grazed. In the better-watered districts autumn-sown cereals, like wheat, barley, and millet, derive enough moisture from the winter rains to be grown without irrigation; and olives, usually found on rocky hill slopes, and vines do not need artificial watering. But citrus and other fruits, cotton and tobacco, all require irrigation.

TURKEY

Turkey is now a relatively small country, about three times the size of Great Britain, with a population (in Asiatic Turkey) of nearly 22 millions. Of her once vast possessions there alone remain to her: (a) the peninsula of Asia Minor and (b) her small European territory. But since Turkey became a republic in 1923 her progress has been rapid. Modern educational methods have been introduced and women have equal rights with men. In many areas farming is now carried on in a scientific way, and though buffaloes and oxen are still widely used for transport and draught purposes, they are gradually being replaced by modern machinery.

Turkey (in Asia) may be divided into (1) the Plateau margined by fold mountains and (2) the Coastal Plains.

(1) *The Plateau* rises from 3,000 feet in the west to 6,000 feet in the Armenian and Kurdistan Highlands. The rivers, flowing in deep gorges, are useless for navigation and difficult to dam for irrigation, though, near Ankara, the Culuk Dam has been built to store water for this purpose and for power. The mountain rim, acting as a barrier to oceanic influences, makes the climate of the interior extreme and dry. No traveller can fail to be impressed by the aridity of the Plateau. Some areas are little better than deserts,

others consist of poor steppes on which sheep and goats are grazed. The famous Angora (Ankara) goats yield a fine curly wool, called mohair, which is an important export. Crops grown in the better-watered areas include wheat, barley, opium, and sugar-beet. *Ankara* (1,120,000), centrally situated on the Plateau, has replaced *Istanbul* as the capital of Turkey.

(2) *The Coastal Plains*, nowhere very wide, margin the Black, Aegean, and Mediterranean Seas. The Black Sea slopes of the Pontic

FIG. 197. Turkey and Trans-Caucasia.

Mountains are forested, the hazel bushes yielding nuts for export. Cereals and figs are grown on the plains, and also tobacco, exported from *Samsun*. Coal mined at *Zunguldak* is used to feed blast furnaces at *Karabuk*, on the railway to *Ankara*.

Similar crops, as well as olives and grapes, are grown in valleys opening to the Aegean, such as those watered by the Menderes and the Gediz, both of which converge on the port of *Izmir* (Smyrna). Silk-worm culture is carried on in valleys opening to the Sea of Marmara, where *Bursa* is the chief centre. In most districts the Taurus rise steeply from the Mediterranean, but where they recede from the sea, as in the Cilician Plain, cotton and tobacco are grown. From *Adana*, the chief town in this area, a railway runs to the ancient port of *Iskenderon* (Alexandretta).

TRANS-CAUCASIA

To the north-east of Turkey are the mountainous Trans-Caucasian states of *Armenia*, *Azerbaijan*, and *Georgia*, all of which form part of Soviet Russia. The mountains are forested, valleys like that of

27. SULTANAS AND DATES

(Above) In this Turkish vineyard workers are gathering grapes, which will be washed, dried (for sultanas) and exported through Izmir. (Below) Date groves, near Basra, Iraq. Incoming tides cause the river to rise and flood the groves.

28 THE JORDAN VALLEY

Note the meanders of the river threading its way through the Rift Valley, and the arid nature of the almost impassable country-side, where the barren hill-sides, devoid of vegetation, show the effects of soil erosion.

the Kura are cultivated. The railway and pipe-line from the petroleum centre of Baku, on the Caspian, follow the Kura valley to Tiflis and thence to the Black Sea port of Batumi (Batum).

SYRIA, LEBANON, ISRAEL AND JORDAN

This region stretches from Turkey southward to Arabia and from the Mediterranean eastward to Iraq. Syria and its smaller neighbour Lebanon are republics, Jordan is an Arab kingdom, and Israel is a Jewish state. Four well-defined zones may be distinguished.

(1) **The Maritime Plain**, bordering the Mediterranean, decreases in width from south to north. The coast, which is rocky in the north and sandy in the south, has few good harbours. Cereals, oranges, grape-fruits, and tobacco are grown on the lowlands, while on terraced slopes are vineyards, olive and mulberry groves. Beirut is the port-capital of Lebanon. Saida to the south is the terminus of the Trans-Arabian Pipe-line (T.A.P.); Tripoli to the north, Baniyas in Syria, and *Haifa*, the chief port of Israel, are terminals of pipe-lines from the Kirkuk oil-field of Irak. Adjoining the ancient port of Jaffa is *Tel Aviv*. (383,000), which though a new town is now the largest in Israel.

FIG. 198. Syria, Lebanon, Israel and Jordan.

(2) **The Western Plateau.** From the plain the country rises gradually to a limestone plateau broken by hills. Nomadic herdsman pasture their flocks on these arid uplands, but the valleys opening to the Maritime Plain are productive. Its associations with three

religions draw pilgrims from many lands to *Jerusalem*: its modern western portion forms the capital of Israel, but the old walled city containing most of the Holy Places is in Jordan.

FIG. 199. Syria, Lebanon, Israel, Jordan.

(3) The Rift Valley is part of that great trough extending from Syria through Israel southward by the Gulf of Akaba to the Red Sea, and thence through Africa. In Jordan the valley forms a deep depression drained by the river Jordan to the Dead Sea, which has no outlet, and whose waters, owing to the great evaporation, are so salt that common salt and bromide are obtained from them on a commercial scale.

(4) The Eastern Tableland, lying east of the Rift Valley, slopes gradually through poor steppes to the Syrian Desert and the Euphrates valley. Wheat is grown round *Aleppo*, whence the railway runs north to Turkey and south through Damascus to Amman. *Damascus*, on an irrigated plain on the edge of the desert, is one of the oldest cities in the world. It is the capital of Syria, and has a population of about 450,000. Damascus is an important route centre: the trans-desert bus service to Baghdad takes 14 hours.

The southern part of the Eastern Tableland, extending through Jordan, is a rugged and semi-desert land, the home of pastoral Bedouin Arabs and fellaheen, who live in scattered oasis-villages. *Amman*, the capital of Jordan, is connected by road with Jerusalem and Baghdad.

After the British relinquished their mandate in Palestine in 1948, the country was partitioned. Most of it fell to the new Jewish Republic of Israel, but the predominately Arab portions were incorporated in Jordan, whose boundaries were extended across the Rift Valley to the Western Plateau.

CYPRUS

The mountainous island of Cyprus, covering 3,570 square miles, lies 60 miles from the coast of Syria. Formerly a British colony, Cyprus became an independent republic within the Commonwealth in 1960. Deforestation in past centuries exposed the hill-sides to soil erosion, but in recent years much land has been planted with trees and now nearly one-fifth of the island is forested. The valleys are cultivated. Crops include wheat and barley, potatoes, oranges, olives, and grapes which are pressed for wine or dried for raisins. A familiar sight in Cyprus, as in many other parts of the Mediterranean, is the carob tree, whose beans are exported. Cattle (including draught oxen), donkeys, horses, and mules are common. Mining is important. Copper and iron pyrites are the main exports, followed by oranges, wine, carob-beans, and asbestos. The chief towns are *Nicosia*, the capital in the centre of the island, and the ports of Limassol, Famagusta, and Larnaca.

EXERCISES

1. Treating Syria, Lebanon, Israel, and Jordan as a whole, indicate on a map the chief natural regions into which this area may be divided. Show how the characteristic occupations in each region are related to geographical conditions.
2. Write an account of Turkey (excluding the European portion) under the headings: Position, Boundaries, Relief and Drainage, Climate, and Products.
3. Select *one* seaboard and *one* inland town from each of Turkey, Syria, and Israel, and in each case describe its situation and the geographical causes that have contributed to its importance.
4. Describe the position of the chief British territories in the Mediterranean and discuss the importance of each.

CHAPTER XX

SOUTH-WEST ASIA

SOUTH-WEST Asia, stretching from Arabia north-eastward through Mesopotamia to the Plateau of Iran, is an arid region where cultivation is almost entirely confined to the river valleys. This vast area forms a transitional belt between the Mediterranean lands and Central Asia. The rainfall, as in the former region, is limited to the winter months, but so scanty is the amount that, as in the even more arid lands to the east, irrigation is essential for the cultivation.

Rarely have peaceful changes come more swiftly to any countries than they have to those fronting the Persian Gulf, which, since the end of the war, have become one of the chief oil-producing areas in the world. Their amazing increase in output is due chiefly to the development of new fields in Saudi Arabia and Kuwait, whose yields of oil exceed those of any other countries in the *Middle East Oil Belt*. It is estimated that at least half the world's proved oil reserves are in this region, which extends from northern Irak and south-west Iran (Persia) southward along the west coast of the Persian Gulf.

The development of the oil industry, due largely to British and American enterprise, has already been accompanied by marked social changes. The companies have built towns for their thousands of workers, who are well housed, well paid, and have good medical services. Moreover, the royalties paid by the oil companies to the governments concerned provide them with enormous revenues. These are available for developing agriculture, improving communications, and for raising the standard of living of peoples who, outside the few towns and cities, are still mainly pastoral nomads or peasant cultivators.

ARABIA

The Peninsula of Arabia—an ancient crust-block—is a plateau rising steeply from the Red Sea, but sloping more gently to the Persian Gulf and the Tigris-Euphrates valley. Most of the interior consists of desert or poor steppe on which nomadic tribes, migrating

according to the season, pasture their flocks. Cultivation and settlement is limited to the seaward margins and to the oases. *Yemen*, in the south-west, which receives some rains from the South-West Monsoon, is noted for its coffee, exported from Mocha. *Oman*, which has a scanty winter rainfall, is noted for dates. *Mecca*, the principal city of Saudi Arabia, is famed as the birthplace of Mohammed. It is linked by road with the pilgrim port of *Yidda*, on the Red Sea, with air services to Cairo, Aden, and the oil-fields of eastern Arabia. From the Arabian oil-field the bulk of the oil is piped to the Mediterranean at Sidon (Saida) in Lebanon, but some is refined locally at Ras Tanura, and some is piped to *Bahrain Island*, a British protectorate, noted for oil.

Kuwait is an independent sheikdom near the head of the Persian Gulf. Formerly a trading, dhow-building, and pearling centre, it is now the fourth oil-producing country in the world, its output coming mainly from the Burgan oil-field.

Aden, a volcanic peninsula in south-west Arabia, is a British colony, a re-fueling station and air base on the route to the Far East, and an entrepôt centre. The adjacent protectorate is inhabited by pastoral tribes.

FIG. 200. Tigris-Euphrates Valleys.

IRAQ

Iraq consists of steppe-desert in the west, and the Mesopotamian lowland, lying between the crust-block of Arabia and the fold mountains margining the Plateau of Iran, and watered by the Tigris and the Euphrates.

Outside the desert area we may divide Iraq into two regions: (1) the low table-land of *Upper Mesopotamia*, stretching from the

Kurdistan Highlands southward to an ancient coastline, running east and west, a little north of Hit (pitch wells) on the Euphrates; and (2) the great plain of *Lower Mesopotamia*, built up of sediment brought down by the Euphrates and Tigris, whose united lower course, the Shatt-el-Arab, is steadily pushing its delta into the Persian Gulf. In spring (March to May) the rivers, swollen by melting snows from the Armenian and Kurdistan Highlands, roll across the plain in heavy flood. In places, as at Hindiya on the Euphrates, barrages have been built to hold back the flood water for irrigation. In other districts where the now embanked rivers have raised their beds above the level of the surrounding land, inundation canals, somewhat similar to those of the Punjab, are led off from the main stream. But much water is raised by old-fashioned water-wheels and modern petrol pumps. Recent large-scale irrigation works include the Samarra Barrage across the Tigris (completed in 1956), designed to store water for irrigation and hydro-electric power, and also to preserve Baghdad, 65 miles down stream, from periodic floods. Dams have also been built across the Great Zab, and other left-bank tributaries of the Tigris, to provide water for irrigation.

Wheat and barley are grown as winter and cotton and tobacco as summer crops. Dates, the chief export crop, come mainly from the riverain belt of the Shatt-el-Arab and the lower Euphrates.

There are *oil-fields* in the Mosul area, and south Khanaqin; but the chief is that of Kirkuk from which oil is piped to the Mediterranean at Haifa, Tripoli, and Baniyas. Fields that began production in 1951 include one north of Basra, and one to the south-west, whence oil is piped to Fao, on the Persian Gulf.

From *Basra*, the chief port of Iraq, river steamers can ascend the Tigris to Baghdad; but the railway first swings up the Euphrates valley and then past the ruins of historic Babylon to the capital, where the line crosses the Tigris by a combined rail and road bridge. For centuries *Baghdad* was a focus of caravan routes between the Persian Gulf and the Mediterranean by the Tigris-Euphrates valley. Today it is a junction for air traffic, and has rail connections with Europe, via Mosul and Uskudar, where trains are ferried over the Bosphorus to Istanbul. Much of Baghdad has lately been rebuilt; with new roads, office blocks, schools, hospitals, mosques, a new airport, and an oil refinery.

THE PLATEAU OF IRAN (IRAN AND AFGHANISTAN)

Shut in on all sides by mountains and lying in the north-east trade wind desert belt, the Plateau of Iran is very dry and its climate extreme, with hot summers and cold winters. There is slight winter

FIG. 201. South-west Asia: Oil-fields.

rain, but precipitation is mainly in the form of snow on the higher mountains. Few streams reach the sea and part of the plateau is an inland drainage area. Politically it is divided into Iran (Persia) in the west, and Afghanistan and Baluchistan in the east.

Iran (Persia), seven times the size of Great Britain, has only some 19 million inhabitants, or somewhat under 30 to the square mile.

That alone provides a key to the arid conditions of Iran, nearly half of which consists of sand and salt deserts, so sterile that they do not even provide scanty pasture for flocks. Of the rest of the country, much consists of poor steppes over which herdsmen wander with their flocks of camels, sheep, and goats, whose wool is used for making rugs and carpets of wonderful colouring and delicate design. In irrigated valleys, such as those in the vicinity of the marginal mountains where snow-fed streams provide water, fruits, vines, mulberry trees, barley, wheat, cotton, and tobacco can be grown. Note the position, close to the mountains, of *Teheran*, the capital, situated on a high plain south of the Elburz Mountains; *Tabriz*; and *Isfahan*, in a valley on the slopes of the Zagros Range.

The district lying between the Elburz Mountains and the Caspian is very different from the plateau. On-shore winds from the Caspian bring rain, which, together with melting snows on the mountains, provides ample water for irrigation.

In Southern Iran there is a major oil-field, in the Karun valley, whence oil is piped to refineries at Abadan, an island port at the head of the Persian Gulf, and ultimately shipped aboard tankers. Including the *Trans-Iranian Railway*, which runs from Bandar Shah, on the Caspian Sea, to Bandar Shapur, on the Persian Gulf, there are about 1,500 miles of rail in Iran. Outside the limited areas so served, communications are carried on mainly by camel and motor caravan.

Afghanistan, the most easterly part of the Plateau of Iran, stretching towards the slopes of the Hindu Kush, and the Pamirs, forms a buffer state between Pakistan and Russia. The greater part of this country consists of stony slopes, arid plateaus with stretches of rough herbage on which feed fat-tailed sheep, and mountains whose snow-clad heights are one of the main features of the landscape. Here and there, in irrigated valleys and plains, are fields of wheat and barley, vegetables, and a variety of fruits including figs, apricots, apples, plums, and cherries.

There are no navigable rivers, no railways, and few good roads. The chief is that from Kabul, the capital, running through the Khyber Pass, to Peshawar (Pakistan). Another road links Kabul with *Kandahar*, whence caravans, with fruit and animals for sale, cross the frontier into Baluchistan on their way to Quetta.

29 LIFE IN CENTRAL ASIA

(Above) A Tibetan with his yak, an animal as useful to him as is a camel to an Arab desert-dweller, or a reindeer to a Lapp (see p. 329). (Below) A Mongol encampment on the steppes of Central Asia. The nomads are pitching their yurts, made of felt stretched over a light framework of poles, which lend mobility to their migrations.

30. SIBERIAN SCENES

(Above) Kuznetsk, an iron and steel centre in Siberia, where many new industrial areas have been established in recent decades. (Below) A Gold Dredger on the Vitim River in Eastern Siberia. Each bucket in the dredger is able to lift from 5 to 10 cwt. of gold-bearing 'earth'. Dredging is merely a large-scale type of placer mining (see p. 333).

CHAPTER XXI
THE HEART OF ASIA
CHINESE CENTRAL ASIA

In the heart of Asia, almost surrounded by mountains, is a region, nearly as large as the United States, which, owing to deficient rainfall, is extremely arid and thinly peopled. The summers are extremely hot, the winters cold. This is Chinese Central Asia, which is divided into three huge territories, Sinkiang (Chinese Turkestan), Inner and Outer Mongolia, and Tibet.

Sinkiang, an arid plateau lying between the Altai Mountains and the Kunlun, is divided into two regions by the Tien Shan, the more southerly forming the Tarim Basin, drained by the Kashgar and the Yarkand, which unite to form the Tarim, a river flowing into the marsh of Lop Nor. Much of Sinkiang consists of steppe-desert, which provides grazing for camels, sheep, and goats. In valleys, irrigated by snow-fed streams descending from the mountains, fruits, cereals, and vegetables are grown. In such oases stand ancient cities, like *Urumchi*, the capital of Sinkiang, Kashgar, and Yarkand, which are entrepôt centres on east-to-west routes between China and Soviet Central Asia.

Mongolia. Most of Mongolia lies in the Gobi Desert, but enough rain falls on its margins to provide grazing for camels, horses, sheep, and goats. The Chinese are opening up Inner Mongolia, where there is an oil-field in the west. Outer Mongolia is under the influence of Soviet Russia. Its capital *Ulan-Bator* (Urga) lies on the new railway from Peking to Ulan-Ude.

Tibet. South of Sinkiang is Tibet, the loftiest plateau in the world, lying between the Kunlun Mountains and the Himalayas. Owing to its great elevation (14,000 to 17,000 feet) the climate is severe. Much of the country is barren desert, but there is some rough pasture in the south where hardy cereals and fruits are cultivated in irrigated valleys. Not only are sheep and yaks the chief transport animals, but their skins provide materials for clothes, their coats yield wool, their flesh is eaten, and their milk is made into butter, an important article of diet in this cold country. *Lhasa*, the capital, in a tributary valley of the Brahmaputra, is the residence of

the Dalai Lama, the head of the Government. Two motor roads link Lhasa with China, one going to Lanchow, the other to Chengtu. Tibet's chief minerals are gold, borax, and salt.

SOVIET CENTRAL ASIA OR RUSSIAN TURKESTAN

Soviet Central Asia, with an area of over a million square miles, stretches from the Caspian to the slopes of the Pamirs and the Tien Shan. Lying far from the ocean, this huge region has a scanty rainfall, and depends for its water mainly on snow- and glacier-fed streams rising in the ranges to the south and south-east. Chief among such streams are the Amu Daria and the Syr Daria flowing into the Aral Sea, whose valleys, with that of the Zeravshan, are the chief cotton-growing area in the U.S.S.R. Between 1934 and 1940 new irrigation schemes enabled the cultivated area to be trebled, but, in order to save unnecessary transport, the bulk of the cotton, formerly sent to mills at Moscow, is now manufactured at *Ferghana*, *Ashkhabad*, and *Tashkent* (490,000), the largest city in Soviet Central Asia. There are oil-fields at *Ferghana* and *Bukhara*, which, like *Samarkand*, stands in the valley of the Zeravshan.

Large non-ferrous metallurgical works, which have been established recently, include a poly-metallic combine at *Chimkent*, and a copper refinery at *Pribalkhash*, which uses copper mined north of Lake Balkhash, and coal from the *Karaganda Coal-field*, one of the newest industrial regions in the U.S.S.R. The Turksib Railway runs from Novo-Sibirsk, on the Trans-Siberian Railway, through Chimkent and Tashkent to Ashkhabad, and thence to Krasnovodsk, on the Caspian.

EXERCISES TO CHAPTERS XX AND XXI

1. Describe the Tigris-Euphrates valley under the headings: (i) Relief, (ii) Climate, (iii) Methods of irrigation and chief crops, (iv) Other important products, (v) Modes of transport, (vi) Chief towns.

2. State in what parts of Asia the camel and the yak are used for transport and similar purposes. In both cases describe (i) how the animal is adapted to the geographical conditions, (ii) the kind of work it performs, and (iii) any useful products obtained from it.

3. Give some account of the occupations of the inhabitants of the Plateau of Iran. With what products does this region supply the outside world?

4. On a sketch-map of the Middle East (a) mark and name the major oil-fields; and (b) mark the pipe-lines through which oil is pumped to ports for export, and name these ports. (c) Write a short geographical account of the petroleum industry in this area.

CHAPTER XXII

THE U.S.S.R.—SIBERIA

MOST of us have some idea of the enormous size of Russia, but not all of us realize that Siberia alone is considerably larger than Europe. Yet this vast territory, stretching from the Urals to the Pacific, and from Turkestan and Mongolia north to the Arctic Ocean, has only a small population. Like Canada, which lies in the same latitudes, Siberia has a continental climate, though one of a somewhat more extreme type than that of the Dominion. The summers are warm, except along the Arctic coast, but the winters are intensely cold. Most rain falls during thunder-storms in the summer months, but though the total amount is relatively small the winter snows compensate in some measure for this, notably in the forest belt, where they lie to a depth of several feet.

Western Siberia, extending from the Urals to the Yenisei river, is a continuation of the Great European Plain. *Eastern Siberia*, like the Canadian and Baltic Shields, is one of the oldest parts of the earth's surface. Rugged and mountainous, it is a huge, much denuded area of ancient (Precambrian) rocks intersected by rivers flowing in precipitous valleys. Between the Yenisei and the Lena is a low plateau, east of which the land rises steadily to the Yablonoi and other ranges of the North-East Highlands.

We may divide Siberia into three well-marked natural regions: the Tundra, the Cold Forest Belt, and the Steppes.

(1) **The Tundra** extend from the Arctic Circle northward towards the Arctic Ocean whose shores are ice-bound for the greater part of the year. For eight months these plains are frozen and covered with snow, but in the brief summer, when daylight is almost continuous, innumerable flowers lighten the dull grey of the mosses and lichens. In spring the ice melts earlier in the upper and middle courses of northward-flowing rivers, like the Yenisei, than it does in their lower reaches, where the water, unable to escape by normal channels, pours over the still frozen tundra, forming marshes and swamps.

The few wandering tribes keep herds of reindeer, which they follow northward in summer towards the Arctic, and southward in winter to the edge of the sheltering forest.

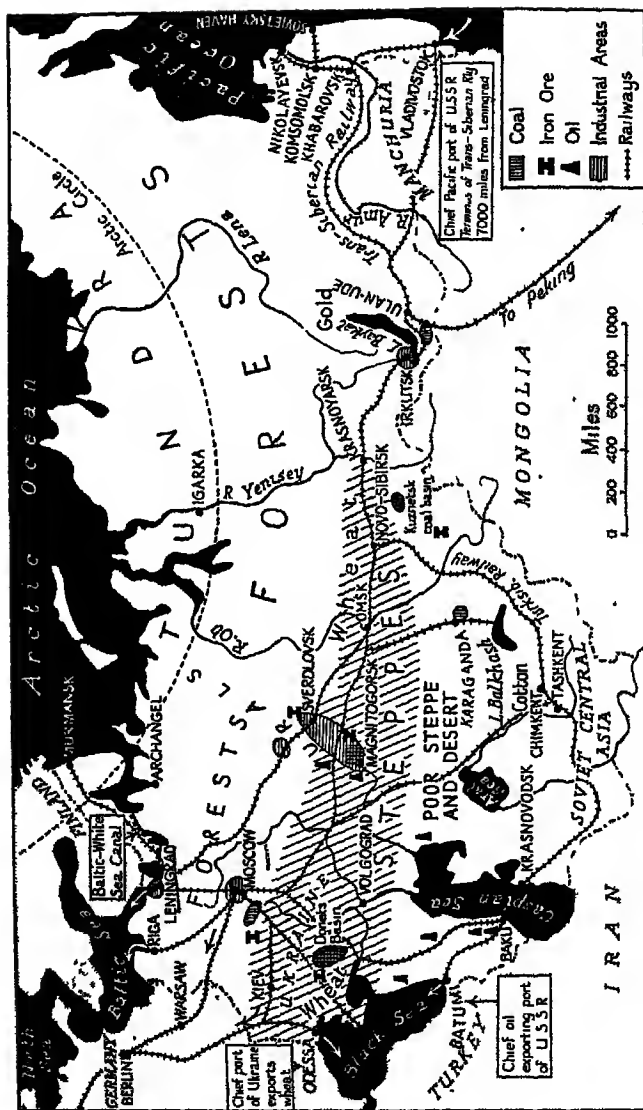

FIG. 202. The U.S.S.R.: Natural Regions.

(2) **The Cold Forest Belt**, the mysterious *taiga*, lying to the south of the Tundra, extends from east to west for over 4,000 miles and from north to south for distances ranging from 1,000 to 2,000 miles. It probably contains about the same amount of marketable timber—spruce, silver birch, and pine—as the Canadian Forest Belt, but as yet, owing mainly to transport difficulties, only some of the more accessible areas on the southern margin, or along such rivers as the Amur, Yenisei, and Pechora (Europe), have been opened up. In late spring and summer, timber is floated down the Yenisei to saw-mills at *Yeniseisk*, or farther down-stream to the port of *Igarka*, whence in summer months it can be shipped to prospective markets by way of the Arctic.

North of Tobolsk, the old horizontal strata are deeply buried beneath recent deposits, which form an imperfectly drained area where, except in winter, transport is extremely difficult. The ancient bed-rock of Eastern Siberia is rich in gold, coal, iron, salt (near Angara), and other minerals, but with the exception of gold little of this wealth has yet been won. The chief gold-fields are the *Lena Gold-field*, on the Vitim Plateau to the north of Lake Baikal, and the *Aldan Gold-fields* still farther north. But owing to transport difficulties it takes two weeks to travel from Irkutsk to the former field, and an additional week to reach the latter. Throughout the eastern taiga much gold is obtained by placer mining, for thanks to prolonged denudation, particles of gold from disintegrated rocks have been concentrated in the beds of streams. The Urals are also rich in minerals, notably iron, coal, and platinum (see p. 218).

(3) **The Steppes** of Western Siberia lie south of the Forest Belt. In most parts the rainfall, though enough for grasses and cereals, is insufficient for trees. Excellent wheat is grown, but owing to the cost of transporting by rail heavy and bulky commodities like grain, farmers tend to concentrate on dairying, which is now the leading industry. Thousands of tons of butter are dispatched in refrigerating cars to Moscow, Leningrad, and other cities of European Russia. It is a long and expensive journey, but the cost is justified, for butter is in great demand and takes up far less room than wheat of equal value. South of the dairying and wheat belt, where the rainfall is less, the land is in the main only suited for rough grazing.

Recent Developments in Siberia and the Far East. Siberia is a territory with enormous possibilities, but until the Soviet

régime little attempt was made at systematic development. This region is served by some of the world's longest rivers, but though the Ob, the Yenisei, the Lena, and the Amur are all navigable, they are frozen for about two-thirds of the year, and only in summer can be used for transport, notably for carrying such bulky commodities as grain and timber.

Many of the older towns, such as *Tobolsk*, at the junction of the Irtysh and the Tobol, rose up at confluence points. With the completion of the Trans-Siberian Railway, recently double-tracked throughout its length, other towns became important because they stood where the line crossed a navigable stream, and where goods brought by water could be forwarded by rail or vice versa. Such a town is *Novo-Sibirsk*, on the Ob, the capital of western Siberia and the junction for the Turkestan-Siberian Railway. However, this town owes its growth in the last few years to the fact that it stands on the margin of the *Kuznetsk (Kuzbass) Coal Basin*, one of the industrial areas that have been opened up in Siberia, whose output is second only to that of the Donetz Basin. Coal is sent to the Ural area and iron ores are brought back to supplement Kuznetsk supplies. The basin is a major centre for iron and steel and chemical industries, and for light metal industries. Its rapid development is shown by the rise in the population of the three largest towns. In 1900 the population of *Novo-Sibirsk* was only 5,000, in 1959 it was 730,000; the mining centre of *Kemerovo* had 21,730 inhabitants in 1936, and 240,000 in 1959; and the population of *Stalinsk*, a major steel centre, rose from under 4,000 in 1936 to 350,000 in 1959.

At *Omsk*, on the Irtysh, the lines from Leningrad via Perm, and Moscow via Chelyabinsk, unite. Thence after passing through Novo-Sibirsk, the railway runs through increasingly wooded country to *Krasnoyarsk* on the Yenisei, and through a still more rugged and forested region to *Irkutsk* (320,000), on the Angara, the chief town in eastern Siberia. Rounding the southern end of Lake Baikal, the line goes through *Ulan-Ude*, the junction for Peking. The main line then continues to Chita, and beyond this town it divides. One branch descends to the Plain of Manchuria, passing through Harbin to Vladivostok; the other, running entirely through Soviet territory, descends the Amur Valley to Khabarovsk, and thence to *Vladivostok*, Russia's chief Pacific port, ice-bound in winter. Large coal and iron mines in the lower Amur Valley provide raw materials

for iron and steel plants near *Komsomolsk* and *Khabarovsk*, whence a railway runs down the Amur to *Nikolayevsk*, which refines oil brought by tanker from the Russian island of Sakhalin.

EXERCISES

1. Describe a railway journey from Leningrad to Vladivostok, paying special attention to (i) the types of scenery and (ii) the natural resources and economic activities of the regions traversed. Give a map.

2. Illustrating your answers by sketch-maps, give an account of (a) the Kuznetsk Coal Basin, and (b) the Far Eastern Industrial Area, i.e. the lower Amur Valley.

TEST PAPER: EURASIA

PART I

1. A delta in Asia has a shore line from 88° E. to 91° E., and is roughly bisected by the tropic of Cancer. Its most northerly area is 26° N. The out-side arms and shore line are almost equal in length. The western arm is used for shipping for about a third of its length to a great city. A great river sends most of its water along the eastern arm. (a) Draw a sketch-map to show the facts stated and (b) explain *one* way in which these facts affect the lives of the people.

2. Examine the photograph of the Lauterbrunnen Valley (Plate 14). (a) What type of valley is this? (b) Draw a contour map to illustrate the characteristic features of such a valley. (c) What effect does the relief have on the occupations of the people living in the valley?

3. (a) What do you mean by the term *map projection*? (b) Name a suitable projection on which to draw a map (i) to show directions correctly, (ii) to illustrate the area of the British Commonwealth, and (iii) to represent Ceylon. Give reasons for your answers.

4. The following statistics give the mean monthly temperature and rainfall for three towns, one in Asia, another on the mainland of Europe, and the third in the British Isles. Suggest, giving your reasons, the area in which each is situated, and state the major climatic region to which it belongs. What type of natural vegetation, and what kind of agricultural products, would you expect to find in the district in which each town is situated?

	Jan.	Feb.	Mar.	Apr.	May	June	July	Aug.	Sept.	Oct.	Nov.	Dec.
A Temp. °F.	42	43	44	47	52	57	60	60	56	50	46	43
A Rain. in. .	2.3	1.9	1.9	1.9	2.0	2.0	2.6	3.0	1.9	2.7	2.7	2.5
B Temp. °F.	75	75	78	82	85	82	80	79	79	81	79	76
B Rain. in. .	0.2	0	0.1	0	0.7	2.1	2.7	1.6	1.2	2.4	0.4	0
C Temp. °F.	52	56	60	64	70	78	85	85	78	68	60	53
C Rain. in. .	2.6	2.0	2.6	1.8	1.7	0.6	0	0.1	0.8	2.4	3.1	2.5

5. Name one country where each of the following animals are used for transport or draught purposes: camels, yaks, elephants, reindeer, water buffaloes. Show how any *two* of these animals are adapted to the work they perform.

PART 2

6. Describe and account for the extent of poor steppe and desert in Eurasia. Describe the way of life of the people in this area outside the large cities.

7. (a) Divide geographical India into *three* major regions. Give the reasons for your division. Select one of these regions and show how the occupations of the people are adapted to their environment.

8. Name (i) a leading port in the Mediterranean, (ii) an entrepôt port in South-East Asia, and (iii) an inland port in Europe outside the British Isles. Draw sketch-maps to show the position of each port and describe its trade.

9. Select one channel of communication from each of the following groups. Describe the kind of scenery you would see in travelling through it, and suggest the kind of trade that passes along it. (a) The Kiel Canal *or* the Manchester Ship Canal; (b) the Khyber Pass *or* the St. Gotthard Pass; and (c) the Rhine Valley *or* the Dardanelles.

10. What geographical conditions favour (a) the development of hydro-electric power in Northern Italy; and (b) irrigation in the Yangtze Valley?

PART 3

11. 'Railway companies usually establish works at places on their own lines, in central positions, where land is cheap, rather than in the vicinity of the coal- and iron-fields from which they can carry supplies at low cost.'

Select two towns in the British Isles which illustrate the above statement, and draw sketch-maps to show their position, in relation to routes, and to the nearest coal-field on the railway system on which they are situated.

12. Divide Scotland into *three* regions. Which is the most densely and which the most sparsely peopled? Show how the relief, climate, and occupations of the people have influenced the distribution of the population.

13. What geographical factors have contributed towards the importance of: (a) Aberdeen as a fishing port; (b) Blackpool *or* Brighton as a sea-side resort; (c) the Clyde as a shipbuilding area?

14. Compare the work of a farmer living in Eire with one in the Fens, and account for the differences.

15. Select *two* inland coal-fields in the British Isles. Describe their position, and name the chief industries (apart from coal-mining) carried on. Select *one* industry from each area and state from whence the necessary raw materials are obtained. Illustrate your answers by sketch-maps.

PART IV

AFRICA

CHAPTER XXIII

GENERAL SURVEY OF AFRICA

Position and Size. Africa is the second largest continent. Its area is about $11\frac{1}{2}$ million square miles, or approximately two-thirds that of Asia, to which it is joined by the isthmus of Suez, now cut by a canal. In former ages Africa was connected with Europe where now are the straits of Gibraltar and Tunis, the subsidence which caused their formation taking place in geologically recent times. As Africa stretches for approximately 35° on each side of the Equator it is crossed by both Tropics: thus the bulk of the continent lies in tropical latitudes. Owing to its shape the portion north of the Equator is much bigger than that to the south. Africa is compact. Unlike Europe, its coasts are almost unbroken, and though Europe is but one-third the size, its coastline actually exceeds in length that of Africa by some 4,000 miles.

Physical Features. Apart from the Atlas Mountains in the north-west, which form part of the old-world fold mountain system, Africa is mainly a huge plateau rising by steep escarpments from narrow coastal plains. A line, slightly convex towards the south-east, extending from the mouth of the Congo to Port Sudan on the Red Sea, divides the plateau into two regions differing in elevation. The north-west portion is a comparatively low plateau—consisting mainly of the Sahara Desert—crossed from south-east to north-west by the Ahaggar Plateau and the Tibesti Highlands. The south-east consists of a much loftier plateau bordered on its seaward side by mountains that are often higher than the interior. This may be divided into the Abyssinian Plateau, of volcanic origin; the Central Lake Plateau in the middle of which lies Lake Victoria; and the South African Plateau whose eastern edge is formed by the Drakensbergs.

The *Eastern Rift Valley* of Africa is part of that running from Palestine through the Gulf of Akaba and the Red Sea, across Abyssinia, past Lake Rudolf, to Lake Nyasa. From the northern end

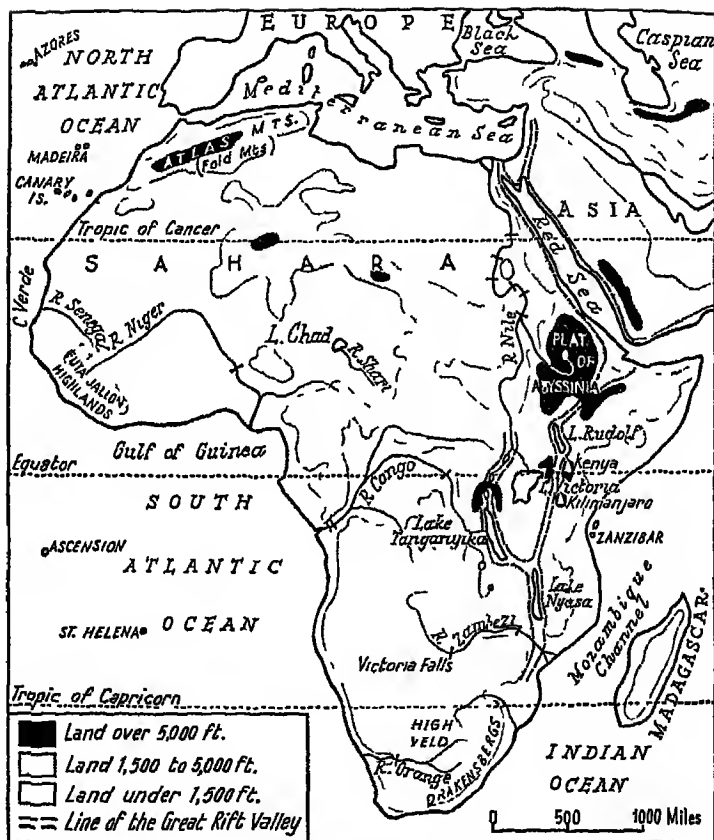

FIG. 203. Africa : Physical Features.

of the latter lake, a branch rift valley runs north-west through Lakes Tanganyika and Edward to Lake Albert. On the east side of the Eastern Rift Valley the extinct volcanoes of Kenya, on the Equator, and Kilimanjaro, some 200 miles to the south, rise to 17,040 and 19,320 feet respectively. Between Lake Albert and Lake Edward the Ruwenzori Range rises to the east of the western rift valley, while south of the latter lake are the Mfumbiro Mountains, with the still-active volcano of Kirunga.

Drainage. The great rivers of Africa are navigable in their courses over the Plateau, but are interrupted by falls where they descend to the coastal plains, and thus are of little use for navigation in their lower courses. Only in the case of the Niger and the Nile are these falls far from the sea; the Nile between Khartoum and Aswan is interrupted by six cataracts at points where belts of hard rock cross the river valley.

The Nile, the longest river in Africa, after emerging from Lake Victoria, flows for some 4,000 miles before it reaches the Mediterranean. Below Berber it traverses a desert region and receives no tributaries. The Congo, 3,000 miles long, drains an area of about 1,500,000 square miles. As much of its basin lies in the equatorial wet belt its volume at certain seasons is much greater than that of the Nile. The Niger (2,300 miles), and the westward flowing Senegal and Gambia, all rise in the Futa Jallon Highlands. The river Zambezi, whose source is not very far from the headwaters of the Congo, has a course of 1,800 miles before entering the Indian Ocean. In South Africa both the Limpopo, flowing into the Indian Ocean, and the Orange, which falls into the Atlantic, are useless for navigation.

About one-third of Africa is an Inland Drainage Region. Lake Chad, into which flows the intermittent Shari, is the centre of a large area of inland drainage lying south-east of the Sahara; Lake Ngami of a similar region in South-West Africa; Lake Rudolf also has no outlet to the ocean.

Climate. Before studying the climatic conditions in detail let us look at a few outstanding factors that influence them greatly.

(1) As three-quarters of Africa lies within the tropics the greater part of the continent is hot, though in many regions, especially in the south-east, the elevation somewhat moderates the actual temperature.

(2) Since the Equator almost bisects Africa we may expect to find

somewhat similar climatic conditions on either side, though we must not forget that the seasons are reversed, and thus, for example, when the north is having its summer, the south is having its winter. There is, it is true, a great climatic similarity, but the actual conditions are somewhat modified by (a) the much greater breadth of the north,

FIG. 204. Africa: July Temperature.

which lessens the oceanic influence in this region, and causes the climatic belts to be more extensive than those in the south; and (b) the presence of the great land mass of Asia to the north-east of the continent.

(3) The cool Benguela Current, flowing northwards along the south-west coast, greatly reduces the temperature of this region. The Canaries Current cools the west coast of North Africa. The warm Guinea Current brings great heat and moisture to the coastlands of the Gulf of Guinea.

Temperature. Examine the July temperature map (Fig. 204).

In *July* the sun is vertically overhead near the Tropic of Cancer and the hottest part of the continent lies north of the Equator, where the temperature over the greater part of the Sahara and the Nile Valley is 90° F. In the Sahara itself, owing to the lack of protective covering and to the absence of cloud, the ground both gains and

FIG. 205. Africa: January Temperature.

loses heat rapidly. Thus the daily range of temperature is great. South of the Equator, July is one of the cool season months. Cape Town has a July temperature of 55° F., and thus is approximately as warm as the north of Scotland in summer.

Gradually the sun appears to move south, and the *heat equator swings south too*, but it moves more slowly than the sun because, though land heats more quickly than water, it still takes some time to become really hot.

In *January* the sun is vertically overhead in the south of Africa, and the hottest regions lie south of the Equator. The belt of

maximum heat, 90° F., is in the south-east. The north is now the coolest part of the continent. The January temperature at Algiers is 53° F., compared with 69° F. (summer) at Cape Town (Fig. 205).

In the equatorial belt temperatures are uniformly high throughout the year, and the annual range is small. Notice, however, that,

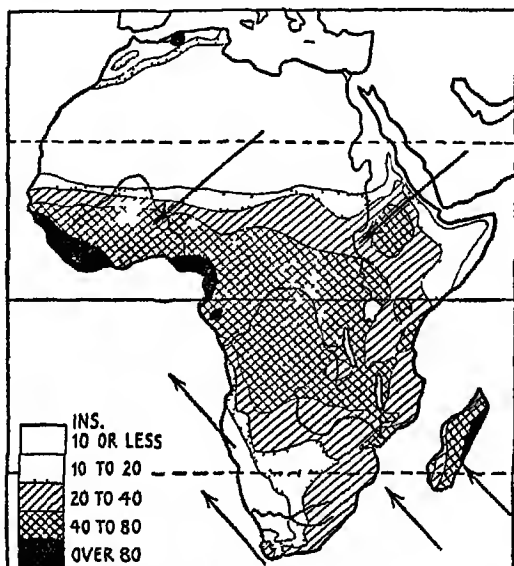

FIG. 206. Africa. Mean Annual Rainfall and Prevailing Winds.

owing mainly to the presence of clouds, the highest temperatures are found near the Tropics and not near the Equator.

Winds and Rainfall. We have seen that the temperature belts move north and south with the sun. Likewise, the pressure, wind, and rainfall belts also move north and south with the apparent movements of the sun; but *though the position of the noon overhead sun varies from $23\frac{1}{2}^{\circ}$ N. to $23\frac{1}{2}^{\circ}$ S., yet the wind belts only move in the same direction about 5° (i.e. 5° N. and 5° S.).*

In Africa, the high-pressure belts, with their outflowing winds, stretch across the north and south of the continent, while the low-pressure belt lies about the Equator. All these belts move north and

south with the sun. The north-east and south-east trades always blow from the high-pressure belts towards the low-pressure belt, and as they are blowing from cooler to warmer regions their capacity for absorbing moisture is increased, and they are dry winds gathering moisture from the land over which they pass. So in Northern Africa the north-east trade winds blowing across a great land mass are dry, and their dryness becomes greater as they pass over the land: hence in the trade-wind zone there is the great desert belt of the Sahara extending from the Atlantic to the shore of the Red Sea. In the high-pressure belt in the south of Africa, the south-east trades blow over the Indian Ocean and on reaching the eastern side of the continent bring rain to the windward slopes of the plateau. The Kalahari arid region is much smaller, both on account of the lesser breadth of the southern part of the continent, and because of the rainy region to the east. Though often termed a desert, the Kalahari is by no means a waterless area, such as the Sahara.

When the trade winds, blowing towards the equatorial low-pressure belt, meet, then the currents of heated moisture-laden air rise, and being cooled by expansion cause heavy convectional rains in this region. Rain falls throughout the year but is heaviest shortly after the equinoxes in March and September. The equatorial rains 'follow the sun', and on both sides of the equatorial wet belt is a zone with summer rains, and a marked dry season which increases in length towards the desert margin.

In the *northern summer* the wind belts have shifted somewhat towards the north. The regions of greatest rain lie north of the Equator: the coast-lands of the Gulf of Guinea and the Cameroons are now two of the wettest parts of the continent (Fig. 207). To the north of this region, a belt of summer rains extends to approximately latitude 16° , beyond which the rainfall diminishes rapidly, practically the whole of the continent lying to the north being rainless. South of the Equator, the high-pressure belt, which has moved northwards, tends to decrease the strength of the south-east trades, and both the interior and the east coast receive comparatively little rain. The south-west, however, now lies in the belt of westerly winds, which have shifted north, and bring winter rains to the region round Cape Town.

In the *southern summer*, climatic conditions are reversed: the wind belts have shifted south. The region of greatest rain lies south of the

Equator in Central Africa, which receives rain not only from the on-shore south-east trades, but also from the winter monsoon winds blowing away from India towards the low-pressure belt over Africa (Fig. 208). In South Africa, the south-east trades also blow strongly on-shore along the east coast, which receives abundant rain, but the

FIG. 207. Africa : Rainfall, May to October.

west coast is rainless, for along it the south-east winds blow off-shore, even as far south as Cape Town, which is having its dry summer season. But North-West Africa now lies in the Westerly Variable wind belt and receives winter rains.

Natural Vegetation and Animals. It has been aptly said that in Africa the vegetation shows that all seasonal change depends on rainfall; and not only do the rainfall belts correspond closely to the Natural Vegetation Zones, but these also correspond to the Major Natural Regions (Fig. 209).

(1) The *Equatorial (or Tropical) Forests*, with their uniformly high temperatures and heavy rainfall, cover much of the Congo Basin and

the coastlands bordering the Gulf of Guinea. Plant growth is continuous, and from the dense undergrowth trees spring up in tiers, some attaining a height of 180 feet or more. Along the east coast is another belt of less luxuriant tropical forest where trees are smaller and undergrowth less dense. Some animals, like the chimpanzee,

FIG. 208. Africa: Rainfall, November to April.

are mainly tree-dwellers; others, such as the hippopotamus, haunt the rivers, while the elephant is found in the more open forest margins.

(2) Except in the western lowlands, the equatorial forests are encircled by *savannas*, where, after the rains, grass springs up in clumps, and trees, such as acacias and baobabs, are of the drought-resisting type. The hoofed animals, like antelopes, giraffes, and zebras, can move swiftly in search of food or when pursued by lions, hyenas, and other carnivores.

(3) Towards the north and south, as the dry season grows longer, the savannas pass into the *deserts*, whose monotonous stretches of rocks, ridges, and wave-like dunes spread to the horizon. Poor steppe

and thorny *scrub* are found on the margins. Date-palms thrive in the oases. The chief animal, the camel, is adapted to withstand the arid conditions.

(4) *Temperate Grass-lands* cover much of the High Veld of South Africa.

FIG. 209. Africa: Natural Vegetation.

(5) *Warm Temperate Rain Forests* clothe the lower slopes of the uplands along the coast of Natal.

(6) *Mediterranean Vegetation*, of a drought-resisting type, is found in the north-west and south-west of the continent.

(7) In Abyssinia and the somewhat higher parts of the Lake Plateau are *Cool Temperate Forests* with upland pastures and mountain vegetation at succeeding elevations.

The Opening Up of Africa. Despite the fact that Northern Africa was early the home of civilized people, the greater part of the con-

continent remained for centuries almost wholly unexplored, and it is only during the last hundred years that it has been 'opened up'.

Why was it so difficult to explore the interior of Africa? The answer is found in the physical features, climate, and vegetation.

The coast-line, almost unbroken and with few good harbours, is bordered by extensive stretches of desert and tropical forests, both of which extend far into the interior. Moreover, the steep escarpments of the plateau, rising behind the narrow coastal plains, together with the falls and rapids which impede navigation in the lower reaches of the rivers, hindered exploration.

The deserts covering nearly half the continent, and the vast unhealthy forests, were difficult to penetrate and are still unsuited for settlement. Vast areas of tropical Africa are almost uninhabited owing to the tse-tse fly, a blood-sucking insect that carries sleeping sickness to human beings, and whose bite is fatal to cattle and other domestic animals.

During the present century there has been an ever-increasing demand by the industrial nations of temperate lands for the products of tropical Africa, which include palm-oil, ground nuts, cacao, cotton, and copra. There is also a call for minerals. Africa has rich supplies of copper, gold, and uranium, and though the amount of coal is relatively small, water-power resources exceed those of any other continent. There is also oil. To avail themselves of Africa's products, and to secure markets for their manufactured goods, the industrial nations of Europe, led by Britain and France, gradually gained control over most of Africa.

The Changing Face of Africa. Vast changes have taken place in Africa in recent years. At the end of the Second World War there were in Africa only four independent states—Egypt, Abyssinia, Liberia, and the Union of South Africa. The rest of the continent consisted of colonies and protectorates of Britain, France, Belgium, Portugal, and Spain, and of Trust Territories of the United Nations. Soon the political map of Africa began to change. By the close of 1958 six additional countries had become independent, namely Libya, the Sudan Republic (formerly the Anglo-Egyptian Sudan), Morocco, Tunisia, Ghana, and Guinea. In 1960 another eighteen countries joined

the ranks of independent states. They were: (a) in West Africa, the Cameroons, Nigeria, Dahomey, Togoland, the Ivory Coast, the Senegal, Mali (formerly French Sudan), Upper Volta (or the Voltaic Republic), the Niger Republic, and Mauritania; (b) in Central Africa, the Chad Republic, the Central African Republic (formerly Ubangi-Shari), the Republic of the Congo (formerly French Congo), Gabon, and the Congo or Congolese Republic (formerly the Belgian Congo); (c) in the Eastern Horn of Africa, the Somali Republic (formed by the union of British Somaliland and the Italian Trust Territory of Somalia); and (d) the Malgasy Republic set up in Madagascar. In 1961 the British colony of Sierra Leone, and the British Trust Territory of Tanganyika became independent. Uganda achieved self-government in 1962 and Kenya in 1963. In the latter year the Federation of the Rhodesias and Nyasaland broke up, and each of the countries composing it claimed the right to full self-government. Thus, except for the colonies of Spain and Portugal, most of the countries in Africa were by 1963 either independent states, or were well on the way towards becoming

EXERCISES

1. Draw a sketch-map of Africa. (a) Shade the high land (approximately that over 3,000 feet). (b) Name the Atlas, Abyssinia Highlands, and Drakensbergs. (c) Insert and name (i) the four principal rivers, marking the chief rapids and falls on each, (ii) lakes Tanganyika, Nyasa, Albert, and Victoria.

2. On a sketch-map of Africa mark and name the Equator and the Tropics, and indicate the principal belts of Natural Vegetation. Describe the natural vegetation of *two* of these belts, lying mainly or wholly in the tropics, and show how it is related to the climatic conditions.

3. Give some account of the chief causes which hindered the 'Opening up' of Africa.

4. Describe, omitting reasons, the general conditions of temperature and rainfall of those parts of Africa which have a Mediterranean type of climate. Name the characteristic crops of such regions, and show how they are adapted to the climatic conditions.

5. Name six of the chief wild animals found on the African savannas, and show how any *two* of them are adapted to the geographical conditions found there.

CHAPTER XXIV COUNTRIES AND REGIONS OF AFRICA

THE MEDITERRANEAN STATES

THOUGH Morocco, Algeria, Tunisia, and Libya have a Mediterranean climate they contain considerable areas of practically rainless and desert lands. The rainfall decreases (*a*) from the Atlantic seaboard eastward (Algiers 30 inches, Tunis 18 inches per annum), and (*b*) from the Mediterranean southward toward the Sahara.

MOROCCO, ALGERIA, AND TUNISIA

We may distinguish three Natural Regions: (1) the Coast-lands and the Tell; (2) the High Plateaux; and (3) the Saharan Margin.

(1) **The Coast-lands and the Tell.** Behind the broken hills that border the Mediterranean and the Maritime Range of the Atlas lies the Tell. It extends from 50 to 150 miles inland, and stretches from Algeria west into Morocco, where it is separated by a barren strip from the coast, and east into Tunisia. It consists mainly of rolling country dotted with hills planted with olive groves and vineyards; plains sown with wheat and barley; and valleys where oranges, lemons, and tobacco are grown on irrigated land. Some of the larger farms are still owned by Europeans who adopt modern methods, but the smaller ones are worked by Arabs whose ways are more primitive. Sheep and goats graze on the uplands, where pastures are broken by stretches of evergreen shrubs and forests of cork-oak, cedar, and squat Mediterranean pines. In Morocco the coastal plain, opening to the Atlantic, produces crops similar to those of the Tell. ✓

(2) **The High Plateaux** lie between the Maritime and Saharan Ranges of the Atlas. Nomadic herdsmen graze their sheep and goats on the poor steppes, while considerable areas are covered with alfa (esparto) grass used for making paper and baskets.

(3) **The Saharan Margin** receives little rain. Date-palms thrive in the oases. Oil-fields have been opened up recently in both the Algerian and Libyan portions of the desert area.

Morocco, formerly under the protection of France and Spain, is now an independent state inhabited mainly by Arabs. The valleys and lowlands facing the Atlantic are the most productive and thickly peopled part of Morocco. From the ancient city of Marrakesh a railway runs through Casablanca, a modern port on the Atlantic, to Rabat, the capital, and on to Tangier, on the Strait of Gibraltar. Phosphates are the chief exports. Imports include motor cars and agricultural machinery.

FIG. 210. Morocco, Algeria, and Tunisia.

Algeria was administered as part of France until 1962, when it became independent. Iron-ore and phosphates (two of the chief exports) are mined chiefly in the north-east and are exported through *Skikda* (formerly Philippeville), a town linked by rail with *Algiers* (870,000), the port-capital. From Skikda a line runs to Biskra and Touggourt, on the edge of the Sahara. Oil-fields in the Algerian Sahara include *Hassi Messaoud*, whence oil is piped to Bougie, and *Edjeleh*, near the Libyan frontier. *Hassi R'Mel* is noted for its vast deposits of natural gas, which is piped to Algiers and *Oran*, the second largest city in the country.

Tunisia, a former French protectorate, is now independent. *Tunis*, on a poor harbour, lies south of the site of Carthage, the great city that once commanded the route from the western to the eastern basin of the Mediterranean. The naval base of *Bizerta* lies to the north-west. Oil is piped from the Edjeleh field to Sekhira, north of the port of Gabes. Besides the Arab population there are French and Italian settlers in Tunisia.

LIBYA

Libya, once the granary of the Roman Empire, was ruled by Italy from 1911 until the Second World War, when the country was liberated by British forces. The greater part was then administered by the British until December 1951, when Libya became an independent Arab kingdom. It consists of Tripolitania, with a population of 800,000, Cyrenaica, with 390,000 inhabitants, and the arid depression of the Fezzan, in the south-west, where 50,000 people live mainly in oases, such as Murzuk.

From the Mediterranean seaboard Libya stretches south to the Chad and Niger Republics, and from the frontiers of Egypt, and the Sudan Republic, it extends west to those of Algeria and Tunisia. Most people live in the coastal belt, where dates, olives, oranges, and vines thrive in the oases. In the steppe zone behind some wheat and barley are grown and nomadic herdsmen find pasture for sheep, goats, camels, and horses. The steppe merges into the sub-desert which produces esparto grass (see p. 349). And beyond spreads the vast expanse of desert, part of the Sahara, where the only fertile spots are the oases. ✓

Tunny and sponge-fishing are carried on in coastal waters. Running along the coast from the frontier of Tunisia to that of Egypt is the strategic road built by the Italians. It is the chief means of communication in the country. In the interior use is made of age-old caravan routes. *Tripoli*, the capital of Tripolitania, and *Benghazi*, the capital of Cyrenaica, are 700 miles apart by the coast road, but only 400 miles by air. Recently oil-fields have been opened up at Zelten, Dahra, and other places, and from them oil is piped to coastal terminals on the Gulf of Sirte. ✓ Libya's chief exports are crude oil, wool, esparto grass, and olive oil. ✓

EXERCISES

1. Draw a sketch-map of the Mediterranean Lands of North Africa, west of the Gulf of Gabes. On your map mark the three natural regions into which this area may be divided. Summarize, in tabular form, the chief products of each region. Describe in detail *one* region.
2. Illustrating your answer by sketch-maps, show how geographical factors have contributed to the importance of the following towns: Algiers, Tangier, and Tripoli.

THE NILE—THE SUDAN AND EGYPT

THE NILE

There is no river in the world quite like the Nile, 4,000 miles long ; for though in the last 1,700 miles of its course it receives no tributaries, yet its waters alone make possible that irrigation without which rainless Egypt would be a desert—part of the vast Sahara.

On emerging from Lake Victoria, the Nile used to flow over the Owen Falls, but a dam has been built across the Falls and a hydro-electric power station erected. In its upper course the Nile has a steady flow for it is fed by equatorial rains stored in the natural reservoirs of the lakes. On leaving Lake Albert, the Nile enters an alluvial plain, being navigable as far as Nimule, on the frontier of Uganda, and the Sudan Republic. Beyond Nimule more rapids prevent the passage of river craft, and the northward journey must be made by the motor-road that runs for about a hundred miles to Rejaf, where it is joined by another road, completed in 1935, from Stanleyville on the Congo. Communication between Rejaf and Khartoum is maintained by steamers which cover the distance in nine days. The Nile constantly broadens into marshes and swamps, beyond which stretch savannas which gradually pass into scrub land as the summer rainfall decreases. In places the fairway is only kept open with difficulty owing to the presence of masses of floating vegetation, called sudd, which block both the main stream and its tributaries. Sometimes the latter are dammed up by the sudd, forming temporary lakes, known as raft lakes. Their life, however, is short, as they dry up owing to the great evaporation. So great is the evaporation in this region that though numbers of tributaries enter the main stream, its volume actually diminishes. About latitude 10° N. the Bahr-el-Ghazal from the west, and the Sobat from the Highlands of Abyssinia, enter the White Nile. Meanwhile the rainfall grows steadily less until at Khartoum it is practically negligible.

At the latter town, the Blue Nile, flowing out of Lake Tana, high up in the Abyssinian Plateau, enters the Nile ; and at Berber the Atbara—the last tributary—joins the river. The heavy summer monsoon rains of Abyssinia cause these rivers to rise rapidly, and rushing down the steep mountain slopes they pour their waters, laden with rich volcanic sediment, into the Nile. The Blue Nile, the

Athara, and minor streams from the highlands, begin to rise in June, and the flood-water reaches Aswan about mid-September, and Cairo a month later. So great indeed is the volume of water brought down by the Blue Nile that this river dams back the main stream, whose waters, thus retarded for a time, reach Egypt in the winter season and so help to preserve a constant flow after the main flood-waters have subsided.

From Khartoum to Aswan the Nile traverses a comparatively narrow valley, and navigation is interrupted by a series of six rapids, called cataracts, where the stream rushes over beds of hard, resistant rock. Below Aswan, the valley grows still narrower, being bordered on both sides by steep cliffs which are from 2 to 15 miles apart. At Cairo, the Nile enters its great delta, crossed by many distributaries, and flows into the Mediterranean through several mouths.

THE SUDAN REPUBLIC

Formerly known as the Anglo-Egyptian Sudan, this country was ruled jointly by Britain and Egypt, but in January 1956 it became an independent state with a republican form of government. With 12,000,000 inhabitants, mainly of Arab, Negro, or mixed Arab-Negro stock, the Sudan has an area of nearly 1,000,000 square miles. Its central portion forms part of the savanna belt extending westward across Africa between the Sahara on the north and the equatorial forests on the south. The whole savanna belt forms the actual *Sudan*, a word meaning 'the land of the Blacks', so called because of its Negro population. Many people are pastoral nomads. Extending from latitude 5° N. to latitude 20° N., the country may be divided into two *Natural Regions*: (1) The *Savannas* of the true Sudan, with high temperatures and heavy summer rains, especially in mountain areas; and (2) The *Scrub and Desert Region*, hot throughout the year with only very light rains in summer; e.g. Khartoum has 3·8 inches of rain in July and August out of a total annual rainfall of 5 inches.

Cotton, the main cash crop, constitutes nearly 90 per cent. (by value) of the country's exports, the bulk being sent to Lancashire. Somewhat more than half the cotton is grown in the Gezira, the district between the Blue and the White Nile, where the construction of the Sennar Dam on the Blue Nile has made possible the irrigation of a considerable area. Cotton is also cultivated on irrigated lands

round Kassala, and as a rain crop in the south. Many dates are grown in the north, while millet is the staple food crop. The Sudan is the chief source of the world's supply of gum arabic—used in the manufacture of confectionery—obtained by tapping the acacias of the southern forests and savannas. Vast herds of cattle are kept by native herdsmen on the savannas; sheep in the somewhat cooler regions, and in the north numbers of humped cattle are bred. The exports of these regions consist mainly of hides, but beef cattle are sent to Egypt, either by rail or river, or via Port Sudan. Gold is mined in the Red Sea Hills and near Port Sudan are salt pans which supply not only the needs of the country, but also furnish a surplus of salt for export. ✓

Khartoum, the capital, at the confluence of the White and the Blue Nile, stands a few miles above the old Dervish capital of Omdurman, the largest town in the Sudan, on the opposite bank of the main stream. From Khartoum the railway runs through Berber to Halfa, the rail-head on the Egyptian frontier, situated below the second cataract, whence there is steamer communication with Aswan. A little north of Berber a line runs to Port Sudan, on the Red Sea, which has replaced Suakin, whose harbour is of little use owing to the growth of a coral reef. By Comet jet aircraft of the British Overseas Airways Corporation (B.O.A.C.) Khartoum is 10½ hours from London (via Cairo) and 10¾ hours from Johannesburg.

EGYPT

Though Egypt has an area of 386,000 square miles, yet nearly all its 25,625,000 inhabitants live in an area covering only 13,500 square miles. This is because the country receives so little rain (Cairo, annual rainfall 1 inch; Alexandria, 8 inches), that the only regions suited for settlement are the delta (Lower Egypt) and the trough-like valley of the Nile (Upper Egypt) where the irrigated belt is from 1 to 10 miles wide. Except for the life-giving waters of the Nile, Egypt would be a desert.

There are two principal methods of irrigation. (1) The older *basin method* is still practised in Upper Egypt, especially *above* the Aswan dam. When the floods begin to rise, in September and October, shallow canals admit the water into embanked fields where it remains until the soil is thoroughly moistened and covered with rich silt. After the waters subside the crops are sown in the wet soil. In

those fields from which the water drains off first, the period preceding the cool winter season is long enough to allow maize to ripen; but in most cases winter wheat and barley—both of which ripen towards the end of April—together with pulses, lentils, and fodder crops like clover, are sown. When the crops have been harvested the land, owing to lack of water, remains fallow until the next flood season.

(2) The modern method allows of *perennial irrigation*. During flood season, the river is held back by dams so that it forms a head of water which is carried by deep canals, below the dam, to many smaller canals and channels. This method was first applied to Lower Egypt by building a barrage at the apex of the delta just below Cairo. Since then other barrages have been built at Asyut, Esna, and Girga, as well as the dam, $1\frac{1}{2}$ miles long, at Aswan. To increase the water available for irrigation a new dam, known as the High Dam, is now being built south of the present Aswan Dam.

By perennial irrigation agricultural production has been enormously increased, for, unlike the basin method, it allows full advantage to be taken of the hot season and so permits such crops as cotton, rice, sugar-cane, and dates to be grown. All these require high summer temperatures and much moisture. Cotton is by far the most important: it supplies 75 per cent. of the total exports of the country, and of this amount about 25 per cent. goes to the U.S.S.R., 12 per cent. to Czechoslovakia, 11 per cent. to China, but only about 5 per cent. to the countries of Western Europe.

In some districts, especially south of Aswan, water is raised by modern oil-pumps. In others, such as the delta, the fellahin (peasants) lift it by means of water-wheels worked by buffaloes or oxen; or even use the shaduf, just as their ancestors did in Bible times. The depression, known as the Faiyum, lying to the west of the delta, is irrigated from the Bahr-el-Yusuf, a stream running out of the Nile. The majority of the Egyptians depend on agriculture for their living. They live in small villages, and there are few large towns.

Cairo (3,300,000), the capital, stands at the head of the delta. *Alexandria* (1,400,000), the chief port, exports cotton. *Mahalla el Kubra*, in the centre of the delta, manufactures textiles. *Port Said* (227,000) lies at the northern end of the Suez Canal.

The Suez Canal, 103 miles long, by connecting the Mediterranean and Red Seas shortens the distance from England to India by

4,000 miles, to Australia by 1,200 miles, and to East African ports by some 2,000 miles. It was opened in 1869. Ships take 11 hours to pass through the canal. About a third of the vessels travelling through it, and a third of the tonnage, is British.

EXERCISES

1. (a) What is the chief cause of the Nile floods, upon which the prosperity of Egypt depends? (b) During what months are the waters of the Blue Nile (i) highest, (ii) lowest? (c) At what season of the year are the waters of the White dammed back by the Blue Nile? Give the reason. What effect does this damming back have on the winter flow of the Nile through Egypt? (d) At what time of the year does the Nile reach its maximum height at (i) Aswan, (ii) Cairo?

2. (a) Name *four* places in Egypt and *one* in the Sudan Republic where irrigation dams or barrages have been constructed. (b) Describe briefly *three* methods of irrigation practised in Egypt. (c) Name the chief crops cultivated in Egypt by the *fellahin* (peasants) during each of the three seasons.

3. Write an account of the Sudan Republic under the headings: relief and drainage, climate, crops and exports.

4. Compare the valley of the Nile with that of the Euphrates-Tigris. State, with reasons, which you consider the more important.

THE SAHARA

The Sahara, greatest of all deserts, lies in the North-East Trade Wind belt (Fig. 212). From west to east it extends for 3,000 miles, and from north to south for 1,200 miles. It is crossed from north-west to south-east by the Ahaggar and Tibesti Highlands. It is difficult to imagine the intense summer heat. The mean July temperature exceeds 90° F. The absence of clouds allows the sun's rays to beat fiercely down upon the bare ground during the day, but at night temperatures fall rapidly, as owing to the clearness of the sky radiation is great, there being few clouds to check the escaping heat. Moreover, the range of temperature is increased by the absence of protective covering. In parts of the Sahara the annual range is as much as 44° F., and the daily range as great as 36° F.

Much of the surface consists of bare rocky plateaux, stretches of stony desert, and vast expanses of sand-dunes swept into wave-like ridges, and cut deep by wadis which are only filled after one of the very rare rain-storms. Though enormous tracts are quite devoid of vegetation, in those regions, chiefly on the desert margins, which

receive 10 inches of rain per annum, thorny scrub and poor pastures are found. Underground supplies of water give rise to oases. Some are quite small. Others, like Kufra or Siwa, are large, having many date-palms and containing several villages. After the date harvest, in September or October, cereals are sown. ~

Minerals include coal mined near 'Colomb-Bechar, and vast deposits of iron-ore worked near Fort Gouraud (Mauritania). From the oil-fields of both Algeria (also a producer of natural gas) and Libya oil is piped to coastal terminals.

Trans-Saharan trade by camel caravans is decreasing, but caravans are used to convey produce, like dates and salt, to railway towns on the desert margins, such as Colomb-Bechar, Touggourt, and Kano in Northern Nigeria. Trans-Saharan transport is carried on by air, and by lorries and motor buses that follow regular routes.

EXERCISE

1. (a) Account for the position of the Sahara. (b) What other deserts are found in similar latitudes? (c) Name *three* oases in the Sahara and *two* products you might expect to obtain from them. (d) Discuss modes of transport.

ABYSSINIA AND THE HORN OF AFRICA

This portion of North-East Africa may be divided into two regions : (1) the Coastal Lowlands, and (2) the Abyssinian Highlands.

(1) **The Coastal Lowlands**, fringing the Red Sea and the Indian Ocean, consist mainly of poor savannas and scrub. Hot at all seasons, they receive little rain. There are no permanent rivers, but in districts where irrigation is possible rice and cotton are grown. Permanent settlement is chiefly confined to the ports, outside which the population consists principally of nomadic herdsmen.

(2) **The Abyssinian Highlands** are composed partly of horizontal lavas carved into plateaux, separated by canyons like those cut by the Blue Nile (flowing out of Lake Tana), Sobat, and Atbara, which flow north-west to the White Nile. The lower slopes of the south-western highlands are clad with forests from which wild rubber and wild coffee are obtained, while in cleared areas cultivated coffee is grown. Much of the higher land is pastoral with some cereal cultivation.

The majority of the people live in the Highlands, where they

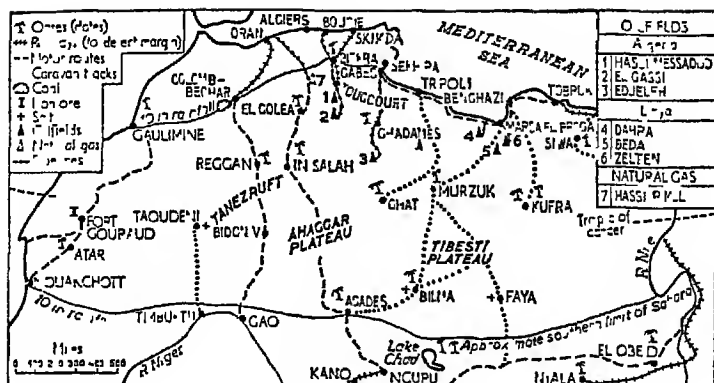

FIG. 212. The Sahara.

FIG. 213. Abyssinia and the Horn of Africa.

dwell in scattered villages. They graze many horned cattle, sheep, and goats, and rear ponies and mules—the chief transport animals—on the rolling grasslands. They merely grow enough food for their own needs, millet being the principal crop. The ground is lightly scratched with a crude wooden plough, drawn by a yoke of oxen, and after harvest the fields are left fallow for some years.

The natural obstacles of a terrain cut by deep canyons make road-building difficult, and many of the roads are rough tracks only good enough for pack-animals. In all there are 11,000 miles of highways fit for motor traffic. Among the roads running from *Addis Ababa*, the capital and chief trading centre, are those going to the Red Sea ports of Assab and Massawa, both in Eritrea, a country federated to Abyssinia. Addis Ababa is also linked by rail with *Djibuti*, the port-capital of *French Somaliland*.

In 1960 the Trust Territory of Somalia and British Somaliland were united to form the independent *Republic of Somalia*. Most of the country is arid and much of the population is nomadic. The port-capital is Mogadishu. From Berbera, the chief port in the north, hides and skins, and sheep and goats are shipped to Aden.

EXERCISE

1. Write an account of Abyssinia under the headings: relief, climate, occupations, transport.

TROPICAL EAST AFRICA

KENYA, UGANDA, TANGANYIKA

This part of Africa consists of the former British colonies of Kenya and Uganda, both now self-governing; the islands of Zanzibar and Pemba; and the former Trust Territory of Tanganyika, independent since 1961.

This portion of Tropical East Africa may be divided into two Natural Regions: (1) the Coastal Plain, and (2) the Plateau.

(1) **The Coastal Plain** consists of a relatively narrow lowland, stretching from the Indian Ocean to the escarpment marking the edge of the Plateau. The mangrove swamps along the coast, the coco-nut palms fringing the sandy shores, the tropical forests, and fields of rice and sugar-cane all attest the hot, wet climate of this region. Climatically *Zanzibar* and *Pemba* form part of it.

31. KENYA AND TANGANYIKA—CHECKING SOIL EROSION

(Above) A newly terraced hillside in Kenya. Terracing helps to check soil erosion, since the rain sinks into the ground instead of running down the slopes and washing away the soil.
 (Below) A tea estate in Tanganyika where the ground has been ploughed and planted along the contours (instead of up and down the slopes), a method that has much the same effect as terracing.

32 SCENES ON THE NILE AND THE ZAMBEZI

(Above) The Owen Falls Dam, where the Nile, flowing out of Lake Victoria, has been harnessed for hydro-electric power. (Below) The Victoria Falls on the Zambezi. The bridge carries the railway from Southern Rhodesia to Northern Rhodesia.

The islands of *Zanzibar* (640 square miles) and *Pemba* (380 square miles) lie off the coast of Tanganyika. The islands produce the bulk of the world's cloves, grown mainly in Pemba, as well as much copra.

FIG. 214. East Africa.

For centuries Arabs have settled in these islands and along the coast of the mainland, where they have mingled with the Bantu. About 275,000 Indians and Pakistanis are found throughout East Africa, where they are engaged in trade and commerce, and occupy responsible positions on the railways and elsewhere.

(2) **The Plateau**, which has an elevation of some 4,000 feet, is cut by the Eastern and Western Rift Valleys. The relatively low-lying district round Lake Victoria is hot, receiving a somewhat heavier rainfall than the rest of the plateau, which has a healthy climate.

The climate has enabled Europeans to make permanent homes in the highlands, notably in Kenya. Other immigrants in recent times are people from India, many of whom are traders.

Near Jinja, where the Nile leaves Lake Victoria, the Owen Falls hydro-electric power plant supplies electricity for homes and industries, e.g. a cotton mill at *Jinja*, where there is also a big smelter treating concentrates from the Kilembe copper mine.

Cotton, and more recently coffee, are the main cash crops in Uganda, where they are cultivated by African farmers. Coffee is grown on hillsides that provide natural drainage. Cotton is often planted on the ridges made by ploughing land across the slopes (contour ploughing), a method which, like terracing, checks soil erosion. In Kenya and Tanganyika millet and maize are staple food crops of the Africans. In Kenya the chief cash crops are coffee, tea, sisal, and pyrethrum, a plant grown for its flowers which are dried and used to make a powerful insecticide. Tanganyika is the world's chief producer of sisal, the main growing area being served by a railway running inland from *Tanga*.

Communications. There are steamer services, on the lakes. The main line of the Kenya and Uganda Railway runs from *Mombasa*, the chief port, through *Nairobi*, the capital of Kenya, and *Nakuru* (branch line to *Kisumu*, Lake Victoria) to *Jinja* and *Kampala*, the chief trading centre of Uganda. Thence the railway runs west to the Kilembe copper mine. From Mwanza, on the south shore of Lake Victoria, another railway runs through Tanganyika to *Tabora*, the junction for the line from *Dar-es-Salaam* (the port-capital of Tanganyika) to *Kigoma*, on Lake Tanganyika. East Africa is well served by air services.

NORTHERN AND SOUTHERN RHODESIA AND NYASALAND

In 1953 Northern Rhodesia, Southern Rhodesia, and Nyasaland were united to form a Federation, but the life of the Federation was short: in 1963 it fell apart and the countries composing it ceased to form one major political unit. The area as a whole has a population of about 8½ million, consisting mainly of Africans, who outnumber the Europeans by nearly thirty to one.

Forming a transitional area between Tropical East Africa and the South African Republic, this region consists chiefly of high plateaux. Though it lies entirely in the tropics it is relatively cool, and receives

most rain in summer. The natural vegetation consists largely of savannas—more thickly wooded in the north than the south—with forests (yielding teak) in the valleys.

Northern Rhodesia is separated from Southern Rhodesia by the Zambezi. The chief crops are maize and tobacco, and the Africans keep many cattle except in the lower valleys, where the tse-tse fly is a limiting factor. There is much mineral wealth. Lead and zinc (Broken Hill) are mined, and copper is of outstanding importance.

FIG. 215. Northern and Southern Rhodesia and Nyasaland.

Mining centres in the copper-belt include Luanshya and Kitwe, and Ndola with a big refinery. Copper ingots are sent by rail for export through either Lourenço Marques or Beira (Mozambique), or, via Elisabethville (Congo) to Lobito (Angola). *Lusaka*, the capital of Northern Rhodesia, lies on the railway running south through *Livingstone*, a town close to the Victoria Falls on the Zambezi. Farther down the Zambezi a huge dam has been built across the Kariba Gorge to harness the river for hydro-electric power.

Southern Rhodesia. The rolling savannas are well suited for stock-rearing and agriculture. Cattle are bred for both beef and dairy purposes. Crops include maize, the staple food crop of the Africans, tobacco, and citrus fruits grown on irrigated lands. Gold ranks next to tobacco among exports. But as the deposits occur in scattered areas, such as those round Gwelo and Salisbury, the

mining is of the 'small working' type. Asbestos and chrome are also mined, and sufficient coal is obtained from the *Wankie* field to supply the needs of both the Rhodesias. *Salisbury*, the capital of Southern Rhodesia, is linked by rail with Lourenço Marques and Beira, both ports being in Mozambique. It is also connected by rail with *Bulawayo*, on the main line from Cape Town to the North, a town with steel works, a sugar-refinery, and flour mills.

Nyasaland lies between the eastern frontier of Northern Rhodesia and Lake Nyasa, and extends down the Shiré Valley almost to the Zambezi. Unlike the Rhodesias the country lacks useful minerals. It is self-supporting in maize and other foodstuffs. Tea and cotton are grown, but they are less important than tobacco, the chief cash crop and leading export. From Salima, near the southern end of Lake Nyasa, a railway runs within easy reach of *Zomba*, the seat of the Government, to *Blantyre*. Descending the Shiré valley to the Zambezi, it crosses the latter river by the Lower Zambezi Bridge on its way to Beira in Mozambique, a port handling much of the over-seas trade of the Rhodesias and Nyasaland.

EXERCISES

1. Name *one* important export of (a) Uganda and (b) Northern Rhodesia. In each case draw a sketch-map to show the chief area of production and the route by which the commodity in question is dispatched to the coast for shipment.
2. Write an account of Southern Rhodesia under the headings: Position and Size, Relief, Climate, Products, Towns and Communications.
3. How do you account for the relatively sparse population in Tropical East Africa? Discuss the advantages and disadvantages of this area and also of Northern and Southern Rhodesia for white settlement.

THE GUINEA LANDS OF WEST AFRICA

Strictly speaking the Guinea Lands are those fronting the Gulf of Guinea, but the term is usually applied to all the West African lands lying between Cape Verde and the mouth of the Congo. With the exception of Liberia, all the countries in this region were formerly colonies of European powers. Now the majority are independent. Of these independent states, Nigeria and Ghana, both members of the Commonwealth, are the most important. The Niger, forming a great arc from its source in the Futa Jallon Highlands to its mouth,

is the main great river, but shorter streams, such as the Senegal and Gambia, follow more or less direct courses to the ocean.

Tropical West Africa falls into two regions: (1) the Lowlands and (2) the Plateau Region.

(1) **The Lowlands**, which stretch along the Gulf of Guinea and the Atlantic, are margined by low, sandy, surf-beaten coasts, fringed by

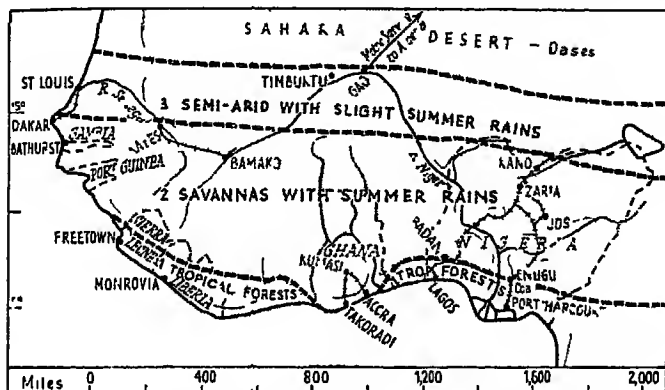

FIG. 216. Tropical West Africa: Natural Regions.

mangrove swamps and devoid of good natural harbours. Great heat, heavy rainfall, with dense equatorial forests, are characteristic of the coastal zone. Such names as the Grain Coast (spice grains), Ivory Coast, Gold Coast (alluvial gold), and the Slave Coast denote the former products of this region; but these names have little more than an historic interest. Today much of the commercial importance of the Guinea Lands lies in their exports of tropical products to the temperate zone, notably to Europe and North America. Chief among these products are palm-oil, palm kernels, and cacao. Nigeria produces nearly half the world's supply of palm-oil and kernels, while Sierra Leone, Ghana, the Ivory Coast, and the Guinea Republic, also yield considerable quantities.

About 35 per cent. of the world's *cacao* (cocoa) is obtained from Ghana, and approximately 15 per cent. from Nigeria. In both countries the crop is produced by African farmers, whose holdings rarely exceed two acres in area. The climate of this part of West

Africa is ideal for the cultivation of *cacao*, a product found only within 20 degrees of the Equator. Cacao requires great heat and moisture, but needs shelter from the winds, and shade to protect it from excessive heat. The flowers spring from 'cushions' on the trunks and branches of the trees; and both flowers and also young and mature pods are seen at the same time. After the beans have been extracted they are either dried in the sun or by artificial means, and then sent by lorry or rail to the port of export.

(2) **The Plateau Region.** The coast-lands rise steeply to the interior plateau, where the natural vegetation is of the savanna type. The Plateau may be divided into (a) the wooded grass-lands of the south, which receive heavy summer rains, and (b) the semi-arid pastoral belt farther north, where the rainfall is deficient and the dry season lasts as long as nine months on the desert margin. The natural vegetation consists of bush with stretches of poor grassland which withers up during the dry season. Vast tracts are inhabited by nomadic herdsmen. Hoe-cultivation is the rule, and when the ground is exhausted, the people clear fresh areas by burning the bush, whose ash, for a time, enriches the soil. The chief crops are cotton, especially important in Nigeria; food crops like maize, millet and Guinea corn; and ground-nuts grown in the drier areas of Northern Nigeria, the Senegal, the Niger Republic, Mali, and the Gambia. The nuts yield a yellow oil used in the manufacture of margarine and the cheaper kinds of salad-oil.

Communications and Political Divisions. Though the Niger is, of course, the chief water-way, most of the rivers can be navigated for long stretches by boats and large steel canoes of shallow draught. There is considerable traffic on the Middle Niger, and small ocean craft can ascend the river to the Fafa Rapids, 400 miles from the sea. Railways run inland from the ports, and air services bring most cities within a 12-hour flight of Europe and South Africa.

Commonwealth Territories. The *Federation of Nigeria* has an area of 350,000 square miles. With about 38 million inhabitants, it has a greater population than any other state in Africa. From *Lagos* (350,000), the Federal Capital and chief port, the railway runs through the forest belt to Ibadan

(600,000), and thence to Jebba, where it crosses the Niger. Northwards, traversing savanna country, it passes through Zaria to the walled city of *Kano*, once the greatest slave market in West Africa, and still a caravan centre to which are brought hides and ground-nuts from the savannas, salt and dates from the desert, to be exchanged for produce carried by rail. From Zaria a railway runs to Jos, a tin-mining centre on the Bauchi Plateau, and thence south, via the coal-mining centre of Enugu, to Port Harcourt. Nigeria's main exports are cocoa, palm kernels, palm-oil, ground-nuts, and tin.

Ghana. The capital is *Accra*. There is a modern deep-water port at *Takoradi*, and a new port at *Tema*, 18 miles east of Accra. But at *Cape Coast*, and smaller ports, goods have to be shipped on board steamers by surf-boats. *Kumasi* is the principal inland town. Gold (alluvial) ranks second to cacao in the export list. *Sierra Leone*, capital *Freetown*, exports diamonds, iron ore, palm-kernels, coffee, and cacao. *Gambia* lies wholly in the savanna region. The capital is *Bathurst*, which exports ground-nuts.

Other Territories, mainly former French colonies but now independent republics, include the *Senegal*, whose capital Dakar is linked by rail (via Kayes on the Senegal River) with Bamako, the capital of *Mali*; and the *Upper Volta* (or Voltaic) and *Niger Republics*. Fronting the Gulf of Guinea are the *Republics of Guinea*, the *Ivory Coast*, *Togo*, *Dahomey* and the *Cameroons*. French Equatorial Africa now appears on the map as the *Republics of Chad*, *Central Africa*, *Gabon* (port-capital: Libreville), and *Congo* (capital: Brazzaville, on Stanley Pool). *Liberia*, a republic founded as a home for freed slaves, exports rubber, iron-ore, and diamonds. Its capital is Monrovia.

EXERCISES

1. (a) Draw a map of West Africa. (i) On it mark and name the Niger and two important tributaries, (ii) indicate and name the principal natural regions, and (iii) mark and name six of the chief ports. (b) Name three important crops grown (i) in the lowlands, and (ii) in the highlands. Describe the conditions necessary for the large-scale cultivation of one crop taken from each region.

2. Describe Nigeria under the following headings: Relief, Climate, Natural Vegetation and Crops, Minerals, Towns, and Communications.

3. Give an account of a journey by a tramp steamer from Bathurst to Lagos, calling at the chief ports *en route*, and state the probable cargoes that might be shipped at each place of call.

THE CONGO BASIN

THE CONGOLESE REPUBLIC (FORMERLY THE BELGIAN CONGO)

Most of the Congo Basin lies within the Congolese Republic, a state (formerly a colony of Belgium) that became independent in June 1960. Independence was followed by a long unsettled period during which intervention by the United Nations became necessary. The Republic has a population of 13½ million.

The Congo drains a circular plain-like basin, whose area is about 1,000,000 square miles. A great part of the basin is over 1,500 feet above sea-level, and it is almost entirely surrounded by the edges of higher plateaux.

The main stream and its tributaries, of which the longest are the Ubangi and the Kasai, lie within the equatorial wet belt, and thus the Congo probably carries more water to the ocean than all other African rivers combined. Owing to the high temperatures and heavy rainfall, at least half the basin is clad with tropical forests. These are especially thick in the lowlands and the river valleys, where oil-palms, mahogany, bamboos, bananas, and rubber-yielding vines rise above the dense undergrowth. In higher areas such as the Katanga Highlands, the forests become more open and pass into wooded savanas. The forests contain useful hardwoods, including mahogany. But such trees are difficult to fell, since they occur in single stands, and their buttress-like roots make it necessary to erect platforms before felling can begin, while even when the trees have been cut through they may not fall, so closely are they surrounded and interlocked with other trees. Thus, though there are in the Congo Basin 6,000 miles of streams suitable for floating logs, lumbering is not of primary importance. Timber is, however, felled for local use, and a certain amount is exported.

Plantation products include rubber, oil-palms, cotton, cacao, and coffee, which flourishes in the Kivu Highlands where slopes are often terraced to check soil erosion.

Cattle thrive only in highland districts, such as Ituri, Kivu, and Katanga, which are free from tse-tse fly, whose bite is fatal to domestic animals and causes sleeping sickness in man.

The Republic has much mineral wealth. ✓ Gold is obtained from

Above this town rapids, extending for some 250 miles, render navigation impossible, and the journey to Leopoldville, on Stanley Pool, must be made by rail. Beyond *Leopoldville*, the Congo is navigable for 1,000 miles to Stanleyville, situated near the base of Stanley Falls, which are avoided by a railway running to *Pontherville*, above the falls. The Congo, now known as the *Lualaba*, is again navigable in two stretches—separated by rapids, but linked by rail—as far as Bukama, linked by rail not only with Elisabethville but with Port Francqui on the Kasai, and Albertville on Lake Tanganyika.

FIG 218. The Congo and N. Rhodesian Copper Belt.

There is a pipe-line from Matadi to Leopoldville for the purpose of pumping oil for use in river steamers plying above the latter town. There are 90,000 miles of motor roads, but many are impassable during the wettest season. One connects Stanleyville with Rejaf on the Nile; another Bukama with Port Francqui.

Internal *air services* connect Leopoldville with Boma, Stanleyville, Luebo, and Elisabethville. Leopoldville is also linked by regular air services with Brussels, via Kano and Tripoli; with Johannesburg; and with New York, via Accra, Dakar, and Lisbon.

ANGOLA (PORTUGUESE WEST AFRICA)

The south-west of the Congo Basin, and the western slopes of the plateau drained to the Atlantic, form Angola (487,788 square miles). On the highlands, cattle, sheep, and goats are grazed; and cotton, coffee, maize, and wheat cultivated at appropriate elevations. In the forests of the coastal lowlands are many oil-palms, with some sugar plantations in the cleared areas. The chief ports are *Loanda*, Benguela, and Lobito. It is possible to travel by rail from Lobito across the continent, via the *Congolese Republic* and the Rhodesias, to Beira in *Portuguese East Africa* (Mozambique).

EXERCISES

1. (a) Describe the climate of the Congo Basin with regard to (i) Temperature and (ii) Rainfall. Explain why the annual range of temperature is so small. (b) Give some account of the Natural Vegetation. (c) Name *five* important cultivated crops, and state why this region is suitable for the large-scale production of *one* of them.
2. Illustrating your answer by a sketch-map, describe the communications of the Congo Basin. So far as you can, account for their development.
3. Compare and contrast the Congo with the Nile under the headings: Relief and Drainage, Climate, Products, Navigation, and Distribution of Population.
4. (a) Draw a sketch-map to show the railway from Lobito to Beira. On your map mark and name the chief towns and name (without boundaries) the countries traversed by the line. (b) Describe the natural resources and the occupations of the people living in the regions crossed by the railway.

THE REPUBLIC OF SOUTH AFRICA

On 31 May 1961 the Union of South Africa became a Republic and relinquished her membership of the Commonwealth. The country covers nearly half a million square miles. It has a population of 15,840,000, including 3,066,000 White people. About 40 per cent. of the White people are of British stock, and the rest are mainly Afrikaners, descendants of Dutch settlers. The former speak English, the latter Afrikaans, a variant of Dutch. Only men and women of pure White descent are allowed to vote or to become Members of Parliament.

Of the non-White people, 10,808,000 are of Bantu origin. Many of the Bantu live in rural areas, and are engaged in pastoral and agricultural pursuits. Some dwell on reserves, and others work on farms owned or managed by White people. Some are employed in the mines, and others as 'unskilled' labourers in the towns. There are also 477,000 Asians, who are chiefly Indians, though some are Malays. Most of the Indians live in Natal, where many are descendants of labourers who came from India to work on the sugar plantations, on which numbers of Indians are still employed. The remaining peoples include 1,488,000 of mixed White and Coloured descent. The majority are found in the south-west of the Cape Province. They are known as 'Coloured' people, a term not applied to either the Bantu or to Asians.

The provinces of the Republic are the *Cape of Good Hope*, *Natal*, the *Orange Free State*, and the *Transvaal*. The seat of the Legislature is at Cape Town; that of the Government at Pretoria. The Protectorates of *Bechuanaland*, *Basutoland*, and *Swaziland* are administered by the British Commonwealth Relations Office.

The greater part of South Africa consists of a high plateau, most of which extends 4,000 feet, with considerable areas rising above 6,000 feet. On the east the plateau sinks through the Drakensbergs,

FIG. 219. South Africa: Relief

whose steep escarpments rise above the East Coast Belt: on the south it descends steeply to the plateaux of the Great Karroo and the Little Karroo. The Orange and its tributary the Vaal rise in the Drakensbergs. The main stream, which flows to the Atlantic in a deep, boulder-strewn gorge, is interrupted by falls, and is useless for navigation, though in some districts its waters are used for irrigation.

The following Natural Regions are distinguished mainly by climate:

(1) **The High Veld**, which forms the eastern part of the plateau, receives summer rains which are heavier in the east and diminish towards the west. Much of this region is a pastoral area where sheep are bred for wool. Oxen and mules are the chief transport animals, for they are not so liable to 'horse-sickness' as horses. Cattle

FIG. 220. South Africa : Natural Regions and Rainfall.

FIG. 221. South Africa : Distribution of Sheep and Cattle.

FIG. 222. South Africa : Distribution of Maize and Citrus Fruits.

are grazed in the wetter areas and sheep in the drier districts. The number of sheep per acre is small, thus the farms are large, and the farmsteads far apart. This isolation accounts in large measure for the independent and rather conservative outlook of the Dutch farmers. Maize, or mealies as it is known, the main cereal crop of the wetter areas, is the staple food of the Bantu. Citrus fruits, especially oranges, and also tobacco, are grown in irrigated valleys in the Transvaal, which has a warmer climate than the south of the High Veld.

(2) **The Western Portion of the Plateau**, which receives even less rain than the High Veld, is a poor pastoral area. The northern part of this area forms the *Bechuanaland Protectorate*, an area inhabited mainly by pastoral tribes. On the west the Plateau sinks to

(3) **The West Coast Plain** which, north of the region round Cape Town, is almost rainless and very sparsely peopled. Its chief economic value lies in its diamonds (see *Minerals*, p. 375).

(4) **The Karroos** are dry treeless plateaux whose surface, strewn with boulders and dotted with small bushes, is broken only by solitary flat-topped kopjes, as the little hills are called. Millions of sheep feed on the Karroo bush, while in the west goats are reared. The former are bred for wool, the latter for their mohair, both products being exported from *East London*, the chief wool market and wool-exporting port of the country. Most of the former ostrich farms have now been replaced by pig and poultry farms.

(5) **The South-West** has a Mediterranean climate. It is the chief fruit-producing region in South Africa, growing oranges, peaches, apricots, plums, and pears; as well as grapes, both for table use and for wine. Much of the land is irrigated, but in many districts fruit and other crops depend entirely on rainfall. This is the chief wheat-growing area in the country, and local supplies are sufficient except in poor harvests when wheat is imported from Australia.

(6) **The East Coast** is a sub-tropical region with rain at all seasons, but mostly in summer when the south-east trades blow strongly on-shore. Within this region three belts may be distinguished:

(a) the coastal zone, where sugar-cane, bananas, and pine-apples are grown ; (b) the higher middle agricultural zone, whose cooler climate favours the production of maize ; and (c) the slopes of the Drakensbergs, which are mainly a pastoral region.

Minerals. Almost half the world's *gold* is obtained from South Africa, where gold accounts for 90 per cent. of the value of the coun-

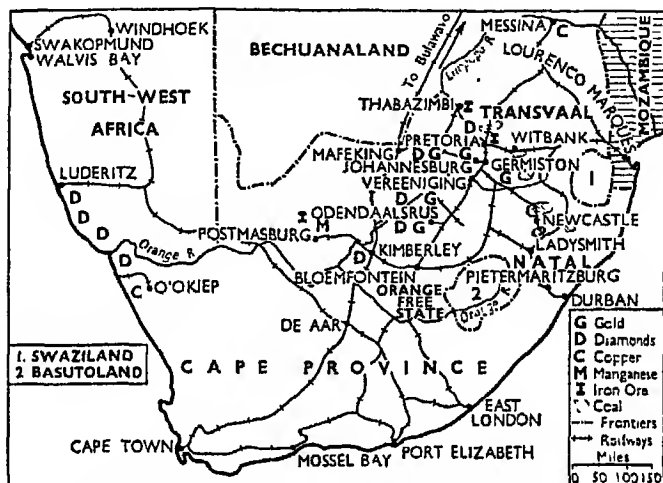

FIG. 223. South Africa : Minerals, Towns, and Railways.

try's exports. The chief producing area is the *Rand* (Witwatersrand), a ridge in the south of the Transvaal forming the divide between the Limpopo and the Vaal. The metal is embedded in conglomerate rocks in extremely fine particles. After it has been hoisted to the surface the rock is crushed, ground by machinery, and chemically treated to acquire the gold. Uranium is now obtained as a by-product. The mines extend for about 40 miles east and west of Johannesburg. There are also important gold mines in the Orange Free State.

Most of the world's *diamonds* come from South Africa. They are obtained from mines at Kimberley, and in alluvial diggings along the west coast, north of the mouth of the Orange River. *Copper* is mined at Messina in the Northern Transvaal. There are vast deposits of *coal*, not of the highest grade, but the seams are

near the surface and are cheap to mine. The chief coal-fields are at *Witbank* (Transvaal), where there is a large thermal power-station which supplies the gold mines with electricity; and at *Vryheid*, in the north of Natal. There are enormous deposits of low-grade iron ore in the *Pretoria* district and even in the town itself. Some of this is used in the iron and steel works of the city, but more important is the high-grade haematite, mined in the Crocodile River valley, 93 miles north-west of Pretoria, where *Thabazimbi* (Native: *thaba* = mountain; *zimbi* = iron) is the principal centre. The mines are 'open-pit' workings. Coal is brought from Natal for smelting the ores, as Transvaal coal is not suitable for this purpose. Iron ore and large quantities of *manganese* ore are mined at *Postmasburg*. The manganese ore is exported through Durban, where there is a separate loading wharf for handling this product.

Communications and Towns. Owing to the configuration of the country the building of railways has been both difficult and expensive; and it is doubtful if many of the lines would have been constructed except for the valuable mineral resources. This is well illustrated by the fact that *Johannesburg* has become the focus of railways and roads from all parts of the country. The main northward line from Cape Town climbs to the plateau, which it crosses in a north-easterly direction to De Aar, an important junction, where one branch runs south-east to Port Elizabeth and another north-west to connect with the South-West African railways. From De Aar it continues north through Kimberley to Mafeking and thence to Rhodesia and the Congo basin. This line, which was built before the Union of South Africa was established, does not pass through the Orange Free State and the Transvaal. From Mafeking, a line runs east and branches (*a*) north-east to Pretoria, and (*b*) south-east to Johannesburg. From the latter town the railway runs east through Germiston (an important junction, 9 miles from Johannesburg) to Witbank, near which it is joined by the line from Pretoria. From Witbank it continues east, through several coal-mining towns, and ultimately crosses the frontier and descends through *Portuguese E. Africa* to *Lourenço Marques*, an important outlet for the Transvaal. From Germiston another line runs south-east, through the Drakensbergs, and descending to the East Coast Belt passes through *Pietermaritzburg*, the capital of Natal, whence it continues to *Durban*,

33 SOUTH AFRICA

(Above) Cape Town with the flat topped Table Mountain in the background. A breakwater protects the harbour from the north westerly gales blowing in from the Atlantic (see p 377).
 (Below) The Groot Constantia, a Dutch colonial house, dating from 1685, in the vine-growing country near Cape Town. Photograph by Jasper Stembridge

34. NIGERIA AND GHANA

(Above) Bags of groundnuts piled up in huge 'pyramids' beside the railway at Kano, Northern Nigeria, awaiting transport to Lagos. Photograph by Jasper Stembridge. (Below) Spreading out cocoa beans to dry on a cocoa farm in Ghana.

EXERCISES

1. Among the products of South Africa are sugar, wine, wool, and maize. Name *one* area important for each product, and describe briefly the geographical conditions that make each area named suitable for the production of the product.
2. Give an account of the railway system of South Africa (including South-West Africa), and show how the position and direction of the lines are related to (i) the relief, (ii) the mineral resources, and (iii) the position of the ports.
3. Draw sketch-maps to show the importance of (i) Cape Town as a port, (ii) Johannesburg as a route centre.

AFRICAN ISLANDS

No one approaching the African islands in the Atlantic can fail to be struck by their mountainous and rugged character. Many rise *steeply from the ocean and culminate in cones which tell of their volcanic origin.*

The Azores, lying some 750 miles west of Portugal, belong to that country, to which they export fruit and vegetables.

The Madeira Islands, some 450 miles west of Morocco, are also a Portuguese possession. Their equable climate favours the production of fruit, grapes for wine, and vegetables, and makes them a favourite tourist resort. *Funchal* is the capital.

The Canaries, a Spanish group, rising from the continental shelf of Africa, attain a height of over 12,000 feet in Teneriffe, the biggest island, on which is situated Santa Cruz, the capital. This port, like Las Palmas, the largest town on Gran Canaria, is a coaling-station.

The Cape Verde Islands (Portuguese) lie in the North-East Trade Wind Belt, about latitude 16° N. Though their climate is drier than the more northerly groups, yet they grow much fruit, together with some cereals and cane-sugar.

The British islands of *Ascension* and *St. Helena* lie in the mid-Atlantic. In the days of sailing-ships they were visited by vessels sailing before the south-east trades; and until the opening of the Suez Canal were still important calling-places for ships *en route* to India. On both islands are cable stations on the England to Cape Town route, which also touches the Cape Verde Islands.

In 1960 the French colony of *Madagascar* became an independent state, known as the Malgasy Republic, population 5 million. Madagascar is separated from Africa, by the Mozambique Channel, 350 miles wide at its narrowest part. Physically the island is a detached portion of Africa and exhibits the same plateau-like configuration. The greater part is a tableland with an average height of from 2,000 to 3,000 feet, bordered by coastal plains. The bulk of Madagascar lies in the south-east trade wind belt, though in the southern summer, when the wind belts have shifted south, the north-east of the island comes under the influence of the north-east trades.

The tropical forests of the wet eastern lowlands are broken by plantations where rice, rubber, cacao, and sugar-cane are grown; while at higher elevations coffee and maize are cultivated. In the drier west the forests are more open, consisting of light tropical woodlands, savannas, and thornwoods. Many cattle are bred in the uplands, and meat-canning is an important industry. Antananarivo, the capital, in the centre of the island, is connected by rail with Tamatave, the chief port.

Mauritius, a British island three times the size of the Isle of Man, lies in the Indian Ocean 500 miles east of Madagascar. Cane-sugar, the most important crop, accounts for one-quarter of the total output of Africa. Most of the sugar grown in Mauritius is exported to the United Kingdom. Aircraft on the service from Johannesburg to Sydney call at Mauritius and the Cocos Islands.

Two other islands, *Zanzibar* and *Pemba*, lie off the coast of Tanganyika (see p. 361).

EXERCISES

1. Draw a sketch-map of Madagascar. (a) Shade the high land. (b) Show, by distinctive arrows, the direction of the prevailing winds in (i) January and (ii) July, and shade the area receiving the heaviest annual rainfall. (c) Print the names of *four* of the chief crops, each over one area, noted for its production. (d) Insert and name the capital and the chief port.

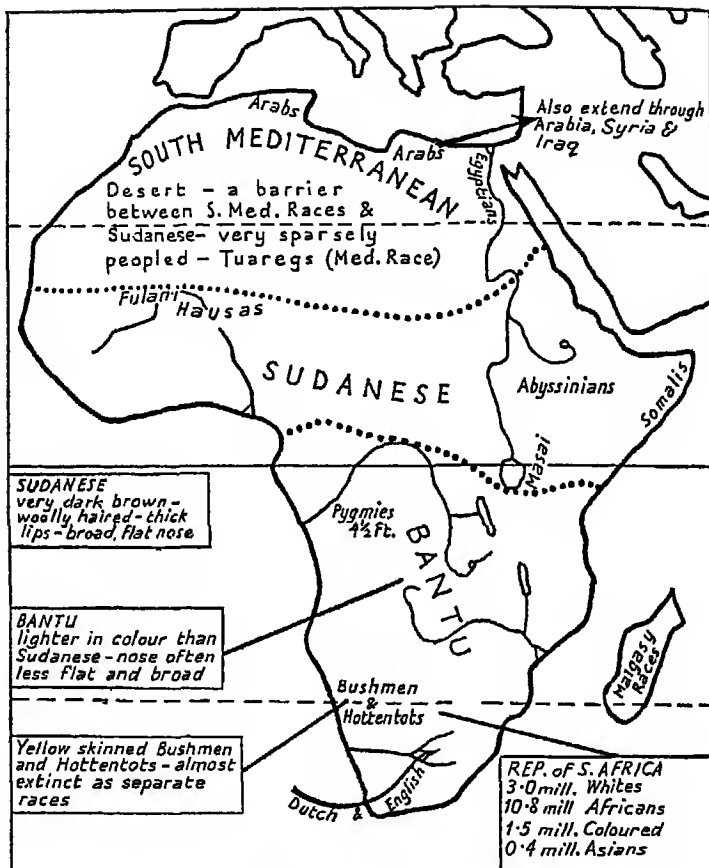

FIG. 225(a). Africa: Peoples.

PEOPLES AND DISTRIBUTION OF POPULATION

The peoples of Africa may be divided into three main groups.

The *South Mediterranean Branch of the White Race* are found mainly in Northern Africa. They include the Berbers, Arabs, and Egyptians, as well as those mysterious folk, the Tuaregs, who live in the Sahara.

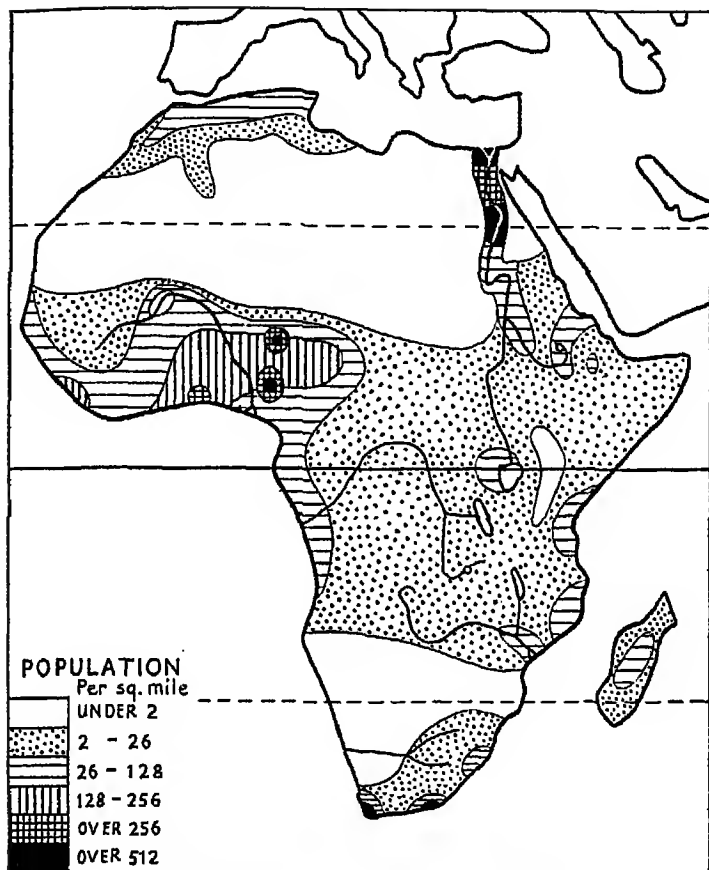

FIG. 225(b). Distribution of Population.

The rest of the continent, apart from the comparatively few people of European origin, is inhabited mainly by Negroes. On the southern and eastern margins of the Sahara, in the Upper Nile Valley, Abyssinia, and along the East Coast there has been a considerable admixture of Negro blood with that of the Arabs and other South Mediterranean peoples. Though the typical Negro is dark, with

woolly hair, and of fine stature, yet some are lighter than others. There are two main divisions. The Sudanese Negroes who, as their name indicates, are found in the Sudan, are very dark brown, with thick lips, and broad flat noses. The Bantu Negroes, inhabiting that part of Africa south of the Sudan, are lighter in colour than the Sudanese, and their noses are usually less broad and flat.

Those primitive peoples, the dwarf Pygmies and Bushmen, have, like other weak races, been driven to take refuge in the less hospitable regions. Both are still in the collecting and hunting stage. The former are found in the heart of the Congo forests: the latter in the Kalahari, where live also the *Hottentots*, herders rather than hunters, who though of mixed origin are akin to the Bushmen.

Africa has a population of 230 millions, an average of 19 to the square mile. No continent shows greater contrasts in the distribution of its population. The Sahara and the Kalahari deserts are almost uninhabited, but part of Egypt is very densely peopled. In the irrigated lands of the Nile valley and delta the number of persons to the square mile in many districts exceeds 1,000, but outside these fertile areas Egypt consists of almost uninhabited desert. The Atlas lands, owing to their climate, accessibility from the Mediterranean, and proximity to Europe, are fairly densely populated, containing a considerable number of people of European descent.

The South African Republic, with an average of 33 persons per square mile, is rather thinly peopled, for its dry climate does not encourage close settlement. The areas of densest population are in the coastal regions, notably round Cape Town, Port Elizabeth, and Durban, together with a thickly-peopled zone in the mining area of Johannesburg. Slightly less than 20 per cent. of the population are of European descent.

The comparatively sparse population of Equatorial Africa, which even in the highlands of Central Africa does not on an average exceed 18 persons to the square mile, is due partly to the past ravages of the slave trade and inter-tribal wars, and partly to the tse-tse fly which by spreading the deadly sleeping-sickness has caused whole areas to be virtually depopulated. In the Guinea Lands, Nigeria and Ghana are, however, much more thickly peopled. Nigeria has, on an average, over 100 persons to the square mile, and in the Niger Basin the number is considerably greater, rising to over 800 to the square mile in some areas. Though Nigeria covers rather less than

one-thirtieth of Africa, it contains about one-sixth of all the people in the continent. In Ghana there is an average of 55 persons to the square mile, but the number rises to about 250 in parts of the coastal belt and in the interior around Kumasi. In Liberia, with an average of 29 persons to the square mile, settlement is confined mainly to the coastal belt.

EXERCISES

1. Describe and account for the distribution of population in Africa, north of the Equator.
2. A traveller journeys from Alexandria up the Nile valley to Rejaf and thence to Banana. Describe his probable modes of transport and the types of people he would see.

TEST PAPER : AFRICA

PART 1

1. Select *one* of the following rivers—Nile, Niger, Congo—and discuss its importance to the people living along its banks.
2. What are the characteristic features of the Mediterranean type of climate? Name two regions in Africa with this type of climate. Describe the natural vegetation and crops of *one* of them.
3. Name *four* important food products, *two* minerals, and *two* raw materials (other than minerals) that Great Britain imports from Africa. Select *one* of these products, say how it is obtained, and describe the route by which it is transported to Britain.
4. Select *one* Commonwealth territory in Tropical Africa and describe it under the headings: position, relief, climate, natural vegetation, crops, and communications.
5. (a) Give an account of the African peoples living south of the Sahara. (b) In what parts of Tropical Africa have white people made permanent homes? Why is Tropical Africa, as a whole, unsuited to white settlement?

PART 2

6. Describe the relief, climate, and natural vegetation of the country you would pass over in a journey by air from Cairo to Johannesburg.
7. Draw a map of Africa to show the tropical forests and the savannas. Show how the native people in each region adapt their lives to their environment.
8. (a) How do you account for the fact that the Sahara Desert extends right across Northern Africa while the Kalahari Desert is limited to the west side of South Africa? (b) Account for the presence of oases in the Sahara, and discuss their importance.
9. Each of the following commodities is an important product exported from the area named: tin from Northern Nigeria, cotton from the

Sudan, copper from Northern Rhodesia, gold from the Transvaal. Choose *three* of these commodities and, for each, draw a detailed sketch-map to show the chief area of production, the name of the producing region or centre, the route by which the product named is sent to the coast for export, and the usual port of export.

10. Select *four* ports in Africa and draw sketch-maps to show their position as regards land and sea routes. Show how the hinterland of each port has contributed to its importance.

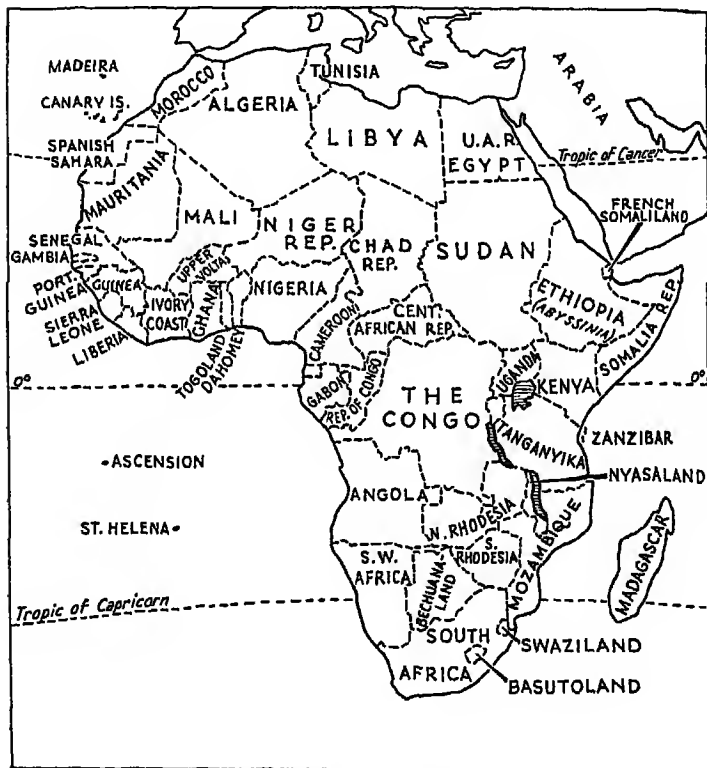

FIG. 226. Africa: Political Divisions.

The map shows the political divisions of Africa in 1963.

PART V
NORTH AMERICA
CHAPTER XXV
GENERAL SURVEY OF NORTH AMERICA
POSITION AND SIZE

WITH an area of 8 million square miles, North America is the third largest continent, ranking after Asia and Africa. The mainland extends from 70° N. to 10° N., or about 4,200 miles ($1^{\circ} = 70$ miles approximately); but as the continent is roughly triangular in shape, by far the greater part lies in the temperate zone. The meridian of longitude 100° W. almost bisects it. North America is separated from Asia only by the Bering Strait, but 1,900 miles of ocean divide Newfoundland from Ireland. Though on the north America faces the Arctic Ocean, it also fronts the Atlantic and Pacific, and is favourably placed for trade with both Europe and Asia.

North America has not such an indented coast-line as Europe, but it has numerous openings. Chief among them are the St. Lawrence, leading to the Great Lakes; Hudson Bay, the Gulf of Mexico, and the Gulf of California.

The coasts vary greatly in character. From the St. Lawrence southward to Chesapeake Bay, the Atlantic coast is a sunken plain, where the mouths of the valleys have become drowned, forming deep and wide inlets at, or near, the head of which stand important ports. South of Chesapeake Bay a low coast, devoid of good harbours, margins a sandy plain. The Pacific coast is bordered by fold mountains, which form a barrier to communication with the interior. In Alaska and British Columbia a sinking coast is indented with fiords. From Puget Sound there stretches southward a straight rising coast, whose only really good harbour is San Francisco Bay.

STRUCTURE AND RELIEF

North America may be divided into four physical divisions: (1) the Canadian Shield, (2) the Appalachians, (3) the Western Cordilleras or Rocky Mountain System, and (4) the Central Plains.

(1) **The Canadian Shield**, which may be regarded as the core of North America, extends in the shape of a huge V (Fig. 228) round

FIG. 227. North America: Physical Divisions.

Hudson Bay, stretching to the south of Lake Superior, and sending an arm westward almost to the Mackenzie River. Slow subsidence and erosion have reduced it to a peneplain which, however, rises in the Labrador Highlands to some 3,000 feet. Its ancient, hard crystalline rocks are rich in minerals, notably nickel, copper, and gold. The bedrock stands out as low ridges above the thin infertile soil. Many

valleys and hollows, dammed up by glacial debris, now form lakes, connected by streams, whose falls are used for power. The rugged undulating Shield differs little in elevation from the adjacent portions of the Central Plains, but it forms a distinct region, owing to its structure and resultant human activities.

(2) **The Appalachians** run from the St. Lawrence southward, roughly parallel to the east coast. They are the remains of ancient fold mountains, much denuded and changed by subsequent earth movements. North-east of the Hudson Valley they form the New England Highlands; to the south they are known as the Central and Southern Appalachians, a system of parallel ridges and valleys, broadest and highest in the mid-south. The Southern Appalachians sink on the east to the Piedmont Plateau, over whose scarped face rivers descend by falls to the Atlantic coast plain. The *Fall Line* so formed is important. The base of the scarp, marking the head of navigation, became a site for towns. The falls provide power.

FIG. 228.

(3) **The Western Cordilleras or Rocky Mountain System** is more extensive and loftier, but of more recent geological origin than the Appalachians. The system extends for some 4,300 miles from Alaska southward to Central America, varying in width from 200 miles to about 1,100 miles. It consists of young fold-mountains, upfolded into three main ranges which, in the extreme south, converge to form a single chain. The ranges are separated by longitudinal valleys or intermont plateaux. The system may be divided into five well-defined sections.

(a) *The Coast Ranges* extend from Alaska to the Peninsula of California. In British Columbia they are submerged, except where their higher portions stand out as islands, such as Vancouver Island. Farther south the Coast Ranges separate the Central Valley of California from the Pacific.

(b) To the east of the Coast Ranges is a series of valleys. In British Columbia these valleys are 'drowned', being represented by the channel running between the mountain wall of the continent and the island-fringe. They are continued by Puget Sound to the Great Pacific Valley and thence into the Central Valley of California.

(c) To the east of the depressions rise lofty ranges known in the north as the Alaskan Range, and farther south as the Cascade Mountains, the Sierra Nevada, and (in Mexico) the Western Sierra Madre.

FIG. 229. North America: Extent of the Ice Sheet during the Glacial Period.

(d) A series of intermont plateaux, lying between these ranges and the main chain of the Rocky Mountains proper, includes the Yukon Plateau, the basaltic Snake River Plateau, the Great Basin of Inland Drainage around the Great Salt Lake, and the Colorado and Mexican Plateaux.

(e) Then come the *Rocky Mountains* proper. Their lofty peaks dominate every landscape. Farther south majestic volcanoes, such

as Orizaba and Popocatepetl in the Eastern Sierra Madre, raise their snow-clad cones high above the Mexican Plateau.

(4) **The Central Plains** cover about three-fifths of North America. Of all the physical divisions of the continent they are at once the youngest and simplest in structure. They are floored with horizontal strata, whose sedimentary rocks were probably deposited on a deeply submerged portion of the Canadian Shield. It is possible to pass from the Arctic Ocean to the Gulf of Mexico without rising more than 1,000 feet. The level or undulating character of their surface is unbroken, except in a few cases where uplands occur, such as the Black Hills of Dakota, and the Ozark Hills between the Missouri and Arkansas rivers.

The plains may be divided into: (a) the *Northern Lowlands*, between the Shield and the Rockies, and drained to the Arctic by the Mackenzie; (b) the *St. Lawrence-Great Lakes Lowlands*; (c) the *Central Lowlands*, drained by the Mississippi, whose elevation is nowhere more than 600 feet, and which merge into (d) the *Gulf Lowlands* which, with the southern part of the *Atlantic coast plain*, form the *South-East Lowlands*; (e) the *High Plains*, stretching from the Central Lowlands towards the base of the Rockies.

THE ICE SHEETS

During the glacial period, great ice sheets spread over North America as far south as latitude 40° N. (Fig. 229). Even to-day the ice sheet has not entirely disappeared, for the greater part of Greenland, as well as a few small areas in Baffin Land, and Devon and Ellesmere islands, is buried beneath it.

The ice sheet did much to mould the surface of the land. It deposited debris, as boulder clay, sand and gravel, which, on account of its wide range of origin, is varied in mineral content and usually forms a fertile soil. In mountain regions glaciers formed U-shaped valleys, and helped to shape the fiords along the Pacific coast. The interruption of drainage, due to the work of ice, resulted in the formation of lakes and falls that to-day provide power for generating electricity.

There were several glacial periods. In the final retreat of the ice the Great Lakes gradually became free, though their natural outlet through the St. Lawrence Valley was still blocked with ice. For a time the lakes drained to the Mississippi, then later by way of the

Mohawk to the Hudson, whose glacier-formed valley is now such an important route. It was not until the Ice Age had finally passed that the Great Lakes were able to send their waters through the St. Lawrence into the Atlantic.

DRAINAGE

North America has a wonderful system of water-ways.

Pacific Drainage. The Yukon, rising in the north-west of the Western Mountain System, though 2,000 miles long, is relatively unimportant, as it is frozen for eight months in the year and flows westward through an almost uninhabited district. Farther south are the Skena and the Fraser, whose valleys are followed by Trans-Continental Railways; the Columbia (1,400 miles) and its tributary the Snake (1,000 miles); and the Colorado, whose famous canyon forms a barrier to communications, but whose waters, like those of the Columbia, have been dammed for irrigation and power.

Arctic and Hudson Bay Drainage. The Mackenzie (2,500 miles) drains Lake Athabasca and the Great Slave and Great Bear Lakes. Like the Yukon, it suffers from the fact that it is only navigable for some four months each year. The Saskatchewan-Nelson (1,900 miles) is the chief river flowing into Hudson Bay; the Saskatchewan flows into Lake Winnipeg, the Nelson carries its drainage into the Bay.

Atlantic Drainage. Chief of all North American rivers flowing into the Atlantic is the St. Lawrence, which, with the Great Lakes, forms a water-way extending for 2,400 miles into the heart of the continent. Farther south relatively short rivers are important because their valleys form routes to the interior, and their estuaries provide harbours on which stand some of the chief American ports. Among these streams are the Hudson and its tributary the Mohawk; the Delaware; and the Susquehanna, the Potomac, and the James River, all three flowing into Chesapeake Bay.

Gulf Drainage. The principal river flowing into the Gulf of Mexico is the Mississippi (2,500 miles), whose basin covers one-third of the United States. After leaving Lake Itasca, a little to the west of Lake Superior, it flows for 400 miles through many small lakes and over numerous falls, of which the last and greatest are the Falls of St. Anthony, below which the river is navigable for small vessels to the Gulf of Mexico. At St. Louis it receives from the

Rockies the Missouri (2,450 miles), whose chief tributaries are the Yellowstone, Platte, and Kansas. Below St. Louis the principal tributaries of the Mississippi are the Arkansas and Red River, whose sources are in the Rockies; and the Ohio, which rises in the Appalachian Plateau.

At St. Louis the Mississippi enters its flood plain, which has a width of from 25 to 80 miles and is margined, in many districts, by bluffs from 200 to 300 feet high. Owing to the slight gradient the silt-laden Mississippi deposits much sediment on its bed. In its lower course the river now flows at a higher level than the surrounding country, which is protected from inundation by earth embankments, called *levées*. So enormous is the amount of sediment carried that the Mississippi has pushed its delta far out into the Gulf of Mexico.

The lower Mississippi and its tributaries, especially the Ohio, are subject to calamitous floods, whose effect is increased owing to the absence of lakes to act as reservoirs. The floods which occur in winter are often due to heavy rain in the north-west Appalachians; those of May to snows melting on the plains; and those of June to snows melting on the mountains and High Plains.

The Rio Grande (2,000 miles) is the only other large river flowing into the Gulf of Mexico.

CLIMATE

In considering the climate of North America the following factors should be noted: (1) Owing to the size of the continent, which extends from the Arctic Ocean into tropical latitudes, there are great varieties of climate with considerable differences of temperature between north and south. (2) Both the Rocky Mountains, and to a much lesser extent the Appalachian, prevent oceanic influences from the Pacific and the Atlantic Oceans respectively reaching the interior. On the other hand, the absence of mountains in the north allows cold winds from the Arctic region to travel far inland, and in winter their effect is sometimes felt as far south as the Gulf of Mexico. But, as if to compensate for this, the absence of a similar barrier in the south permits the moderating effect of the ocean (Gulf of Mexico) to be felt in the Lower and Middle Mississippi Basin.

Temperature. The *winter* isotherms run from west to east, bending south over the interior, which is colder than the coastal

regions. The January isotherm 32°F. shows that most of the northern part of the continent has a temperature well below freezing-point. The west coast is warmer than the east, for the prevailing south-west winds blowing from the Pacific raise its temperature.

FIG. 230. North America: January Temperature.

Along the east coast the prevailing winds blow from the cold land interior, thus decreasing the temperature. Even in winter the Great Lakes, though frozen round their shores, have some moderating effect on temperature.

Note the effect of the ocean currents. In winter the warm Gulf Stream raises the temperatures along the south-east coast of the United States. The cold Labrador current lowers the temperature along the coast of Labrador; while the cool Californian current reduces temperatures along the west coast.

In *summer* the interior of the continent gains heat rapidly because the north to south mountain barriers, especially the Western Mountain System, shut out oceanic influences. The coastal regions are now cooler than the interior. The July isotherms are slightly convex

FIG. 231. North America: July Temperature.

towards the north, but the east coast is now warmer than the west. Along the northern part of the Pacific coast the on-shore westerlies are relatively cool, but along the east coast blow off-shore as warm winds. The Great Lakes exert a cooling influence. Note that the south of the continent, as well as the West Indies, has a July temperature of over 80° F., while in the south-west the temperature of the interior exceeds 90° F.

Winds and Rainfall. As the bulk of North America lies in the westerly wind belt there is, over the northern part of the continent,

a general movement of air from west to east. The Pacific littoral of Alaska, British Columbia, Washington, and Oregon (U.S.A.) receives a heavy rainfall from the on-shore westerlies at all seasons, but especially in winter. The Rockies, in addition to the rainfall on their

FIG. 232. North America: Winter Rainfall and Winds.

windward slopes, receive, on account of their elevation, much precipitation in the form of snow. In winter most of the continent north of the January isotherm 32° F. is snow-clad. On the leeward side of the ranges comprising the Rocky Mountain System there is a marked rain shadow because the winds, having deposited their moisture on the western slopes of the mountains, blow as dry winds. In Alberta the Chinook winds, descending from the Rockies, are warmed by compression, and have a great warming and drying

effect (sec pp. 61 and 408). The rainfall of the intermont plateaux, enclosed as they are by high mountain barriers, is small.

The High Plains on the eastern side of the Rockies are dry. The Central Plains receive much more rain, and beyond longitude

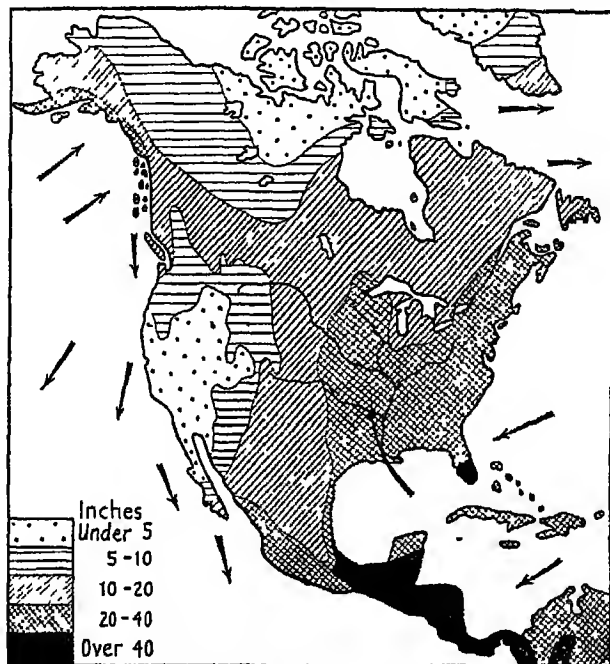

FIG. 233. North America: Summer Rainfall and Winds.

100° W. the rainfall increases both to the east and towards the Gulf of Mexico. The Great Lakes also cause an increase in their immediate neighbourhood. The regular rainfall of this area is largely due to cyclonic storms which pass over the Lakes and down the St. Lawrence valley to the Atlantic. In summer the low pressure system over the interior causes winds to flow in from the Atlantic. The effect of this low pressure, with its inflowing air, is especially marked in the south-east of the United States, where the north-east trade

winds are deflected, and are drawn on-shore and up the Mississippi Valley, causing heavy summer rains. In the Central Plains the maximum rainfall occurs in early summer: on the south-east and Gulf coast-lands it is in early autumn.

FIG. 234. North America: Vegetation Zones.

During the northern winter, the wind and rainfall belts move south with the apparent movement of the sun. At this season Central California lies in the westerly on-shore wind belt and receives rain. The Mediterranean Climate of this region is well illustrated by Sacramento, which receives 17 inches of rain (out of an annual total of 19 inches) in December, January, and February, but practically none during June, July, and August, when the winds, whose general direction is north-east, blow off-shore or parallel to the coast.

Mexico, Central America, and the West Indies lie in the North-East Wind Trade Belt. The windward sides of the mountains receive heavy rain, especially in summer, when the trade winds are strongest. The West Indies, and also the south-east of the United States, suffer from tropical cyclones, called hurricanes, which at times do great damage.

NATURAL VEGETATION

The chief vegetation zones of North America are well marked, but it should be remembered that these zones gradually merge into one another, and that over extensive areas the natural vegetation has been greatly modified by Man (Fig. 234).

(1) *The Tundra*, known in North America as the Barren Lands, extend right across the extreme north of the continent.

(2) *The Coniferous Forest Belt* spreads south of the tundra, stretching for some 3,000 miles from the Atlantic to the Pacific, and having an average breadth of some 600 miles. The chief trees are spruce, birch, balsam, and red and white pines. The forests of British Columbia are noted for their magnificent Douglas firs.

(3) *Mixed Forests* of deciduous trees and conifers are found in Eastern Canada and the North-Eastern United States. Among the chief broad-leaved trees are beech, ash, elms, and sugar maples.

(4) *The Prairies* form a wedge-shaped region, narrowing southward, extending from the Coniferous Forest Belt through the Central Plains to the Gulf of Mexico.

(5) *The Desert and Semi-Desert Region* extends from the Gulf of California northward through the plateaux of the United States, between the central and main range of the Rockies, and southward into Mexico.

(6) *The Mediterranean Region*, with evergreen trees and shrubs able to withstand the summer drought, is found in Central California.

(7) *Sub-Tropical Evergreen Forests* occur in the South-Eastern United States. One of the most useful trees is the long-leaved or yellow pine, whose wood is used in making floors, doors, and furniture. In swampy areas cypresses abound.

(8) *Tropical Forests* clothe much of the hot, wet, coastal belts of Mexico and Central America.

AGRICULTURAL AND PASTORAL BELTS

In a continent so large as North America, there are vast areas where climate and relief vary little, and where the same kinds of crops can be grown. The chief agricultural and pastoral belts shown in Fig. 235 well illustrate the influence of climatic factors.

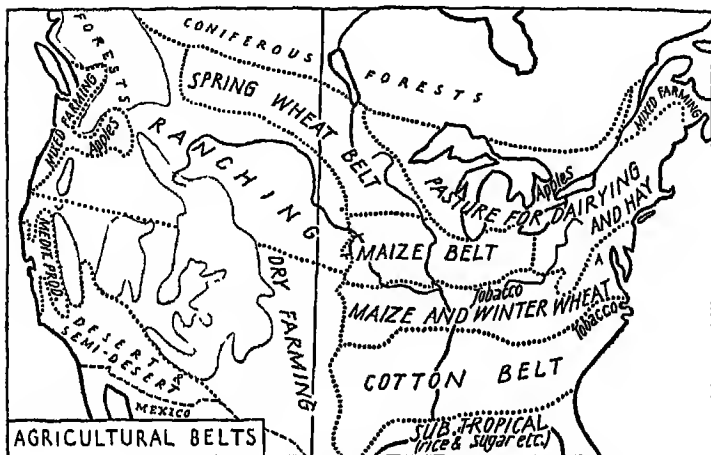

FIG. 235. North America : Agricultural Belts.

(1) *The Spring Wheat Belt* extends from Central Canada to the middle Mississippi. The winters are long and severe, the summers short but warm and sunny, and the rainfall is moderate.

(2) *The Maize Belt.* South of the spring wheat belt, the less severe winters, the longer and hotter summers, and the greater rainfall provide ideal conditions for the cultivation of maize.

(3) *The Maize and Winter Wheat Belts.* In this belt, as its name implies, the winters are sufficiently mild to allow autumn-sown wheat to survive the winter months.

(4) *The Cotton Belt* is bounded on the north by the invisible line marking the limit of 200 days free from frost, and on the west, in general, by the meridian 100° W. beyond which the rainfall is insufficient for cultivation without recourse to irrigation.

(5) *The Sub-Tropical Belt*, fringing the Gulf of Mexico and

including the Peninsula of Florida, produces sugar-cane, rice, and warm temperate and sub-tropical fruits.

(6) *The Ranching and Dry Farming Belts* lie in the region of scanty rainfall stretching from longitude 100° W. to the Rockies.

(7) *The Dairy Pasture, Hay and Mixed Farming Belt* lies south of the coniferous forests in the region round the Great Lakes and extends north-eastward through the St. Lawrence Lowlands. The relatively damp climate favours dairying, and the many towns provide a ready market for produce.

(8) In *the Mediterranean Region* of Central California enormous quantities of warm temperate fruits and vegetables are grown on irrigated lands.

(9) In *Mexico and Central America* the type of cultivation depends mainly on altitude.

PEOPLES OF NORTH AMERICA

When the first Europeans reached America they found it inhabited by copper-coloured people, with straight black hair, broad cheeks, and long, well-shaped noses, to whom they gave the name of Indians (p. 75). These people were at various stages of culture; some were merely food-gatherers or hunters, but others practised simple agriculture. Apart from some districts along the north coast of North America, where lived Eskimos, possibly of Mongolian origin, these so-called Indians were spread through both the Americas. At first they received the white men kindly, but later there was constant strife between the two races and the Indians steadily decreased in numbers. To-day in Canada and the United States large reserves have been set aside for the Indians, where they can follow their traditional occupations. Much is also being done to educate them and improve their health and general well-being.

It was not until about a century after the time of Columbus that Europeans began to make their homes in the northern continent. French pioneers settled along the St. Lawrence estuary, where their descendants still live to-day; the Dutch established themselves at the mouth of the Hudson, the British around Chesapeake Bay and in other districts between the Appalachians and the Atlantic coast. Meanwhile French colonists, who had penetrated up the Mississippi Valley, tried to prevent the English settlers along the coast from spreading into the fertile plains to the west. The French lost their

possessions in Canada, which were surrendered to the English a few years after Wolfe's victory at Quebec (1759). Some twenty years later, the thirteen English colonies along the Atlantic seaboard won their independence and formed the nucleus of the United States.

FIG. 236. North America: Early Exploration.

The Spaniards, seeking gold and precious stones, turned their attention to Mexico and Central America, where the majority of the people are of mixed Spanish and Indian descent; while the whites are mainly of Spanish origin.

Emigrants from all the countries of Europe subsequently settled in North America, especially in Canada and the United States, where, with English as their common tongue, two great nations live side by side. In both countries, especially along the Pacific coast, there are a number of Japanese and Chinese; as well as Indians; and in the United States live some 15,000,000 Negroes (found mainly in the south) who, like most of the inhabitants of the West Indies, are

descendants of former slaves brought from Africa to work on American plantations.

EXERCISES

1. Illustrating your answers by diagrams, where necessary, and giving examples from North America, (i) state how *fold-mountains*, *residual mountains*, and *peneplains* are formed. (ii) What do you understand by an alluvial plain? Of the above types of land-forms, state which you would expect to be most thickly peopled and why.

2. On a sketch-map of North America, (i) shade the land over 3,000 feet; (ii) insert and name the Rockies, Appalachians, and Plateau of Labrador; (iii) name the St. Lawrence and insert and name the five Great Lakes; (iv) insert and name six of the chief rivers in addition to the St. Lawrence; (v) mark and name the Tropic of Cancer and longitude 100° W.

3. (a) What effect have the Rocky Mountains on the climate of the Central Plains? (b) How does the absence of mountain barriers on the north and south of North America affect the climate of the Interior Plains in (i) winter, and (ii) summer?

4. The climatic data below refer to Port Simpson (B.C.), Sacramento, and Winnipeg. State, giving your reasons, to which town each refers, and classify the climate of each as Maritime, Continental, or Mediterranean.

Town	Coldest Month	Hottest Month	Rainfall	
			Nov.-Apr.	May-Oct.
A	34° F. (Jan.)	57° F. (Aug.)	41 in.	40 in.
B	— 3·5° F. (Jan.)	66° F. (July)	6 in.	14 in.
C	46° F. (Jan.)	73° F. (July)	17 in.	2 in.

5. On a sketch-map of North America, insert and name the chief belts of Natural Vegetation. In the case of *one* of these belts, state briefly the relationship between the natural vegetation and climate.

6. (a) Give an account of the peoples living in North America at the time it was first discovered by European explorers. (b) What peoples, other than native inhabitants and those of European descent, are now found in North America? Account for their location in those areas in which they are chiefly found.

CHAPTER XXVI

CANADA

WITH an area of 3,845,000 square miles, Canada is the largest single state in the British Commonwealth, but though nearly thirty times the size of the British Isles its population is less than one-third that of these islands. Why has this vast Dominion a relatively small number of inhabitants? In part, because the North-West Territories and Yukon (comprising somewhat more than one-third of Canada) are climatically unsuited to close settlement: in part, because Canada is a 'new' country. It is true that Quebec was colonized by the French early in the seventeenth century; and that some hundred and fifty years later, when Canada passed to Britain, Ontario received many settlers from the home country and the United States, yet in spite of this early colonization it is only during the last century, and more especially during the last fifty years, that Canada has been steadily opened up. The year 1885, when the Canadian Pacific Railway was completed, may be regarded as marking the beginning of an era of expansion. The construction of this transcontinental line made possible the development of the prairies, and by linking Eastern Canada with British Columbia strengthened the ties between these widely separated regions. So rapid has been the progress of the Dominion in the present century that in 1962 the population was over three times as much as in 1901. In 1962 out of 18,200,000 people, approximately half were of British origin and a third were of French descent. Apart from 125,000 Indians and Eskimos and a number of Chinese and Japanese, the remaining inhabitants of Canada are of European stock, with a high proportion of Germans, Scandinavians, Ukrainians, Dutch, Poles, and Italians, many of whom dwell in the prairie provinces. As about 80 per cent. of the Canadians live within 200 miles of the United States frontier, and the majority much nearer, it is not surprising that there is much coming and going across the border, and that the ties between the two countries are exceptionally close.

Canada has enormous forest, mining, and agricultural resources. She produces a certain amount of coal and oil, but has much developed hydro-electric power, in the output of which she ranks

second only to the United States. She is also a great manufacturing nation; her industries gained impetus during the last war.

Canada may be divided into six regions: (1) the Atlantic Provinces, (a) Newfoundland, and (b) Prince Edward Island, Nova Scotia, and New Brunswick; (2) the St. Lawrence-Great Lakes Lowlands; (3) the Coniferous Forest Belt; (4) the Prairie Provinces; (5) the Arctic and Sub-Arctic Regions; and (6) British Columbia, fronting the Pacific Ocean.

(1) *a. Newfoundland* joined Canada in April 1949. Lying at the entrance to the St. Lawrence, its rugged coasts are cut by many inlets and by long winding fiords. The chief wealth of the island lies in its forests, fisheries, and iron mines. Pine, spruce, birch, larch, and other softwoods cover about one-quarter of the interior, yielding timber for pulp, which is manufactured into paper at Cornerbrook and Grand Falls, where the Middle Exploits river provides power.

South and east of Newfoundland the broad Continental Shelf, covered with comparatively shallow water, forms the *Grand Banks*, one of the chief fishing grounds in the world. The cold Labrador Current brings diatoms and other food suitable for fish. The chief catch is cod, which form 80 per cent. of the fish exports, but hake, halibut, and herring are also caught. Much dried cod is sent to Brazil, the West Indies, and the Catholic countries of Southern Europe. Much cod is also exported in frozen form. *St. John's*, the capital, is a centre of sealing-vessels, which in early spring hunt for seals on the ice-floes. Seal-fat yields oil used in making soap; the skins are tanned for leather. Much of the iron-ore mined at Bell Island, in Conception Bay, is sent for smelting to Sydney, Cape Breton Island. *Gander* is a trans-Atlantic airport.

(1) *b. Prince Edward Island, Nova Scotia, and New Brunswick* were formerly known as the Maritime Provinces. Prince Edward Island is the smallest but most densely peopled province in Canada. Somewhat isolated from the rest of Eastern Canada, these three provinces belong to the same natural region as the adjacent New England Region of the United States.

The chief occupations are fishing, mixed farming, lumbering, and mining. The damp climate favours dairying and the growing of cool temperate fruits, especially apples, for which the Annapolis Valley, on the east side of the Bay of Fundy, and that of the St. John river

(N.B.) are noted. Dairying and poultry farming are especially important in Prince Edward Island. New Brunswick is noted for lumbering. Nova Scotia is the leading *coal-mining* province in Canada, accounting for some 40 per cent. of the Dominion's output. The chief mines, near *Sydney*, in Cape Breton Island, are close to the coast, thus facilitating export, and the import of ore from Newfound-

FIG. 237. Canada: Regions.

land for iron smelting. The ice-free ports of *St. John* and *Halifax* are terminal ports of the Canadian Pacific and the Canadian National Railways respectively.

(2) **The St. Lawrence-Great Lakes Lowlands.** The St. Lawrence Lowlands are level plains lying between the rugged forested lands of the Canadian Shield and the Northern Appalachians. They are covered with thick glacial drift, whose sandy and clayey soils form excellent agricultural land. Parts are still wooded, but outside the urban areas mixed farming predominates, the growing of oats, hay, potatoes and other root crops being closely associated with stock-rearing. Somewhat more than half the dairy cows, sheep, pigs, and poultry, and nearly half the beef cattle in Canada, are found in the two provinces of Quebec and Ontario. On many farms vetches, clovers, and green maize are stored in silos for food during the winter,

which is too severe for stock to remain out of doors. Dairying has the advantage of a ready market close to hand, and an overseas market in England, which obtains more cheese from Ontario than any country. The Lake and Niagara Peninsulas are noted for fruit farming,

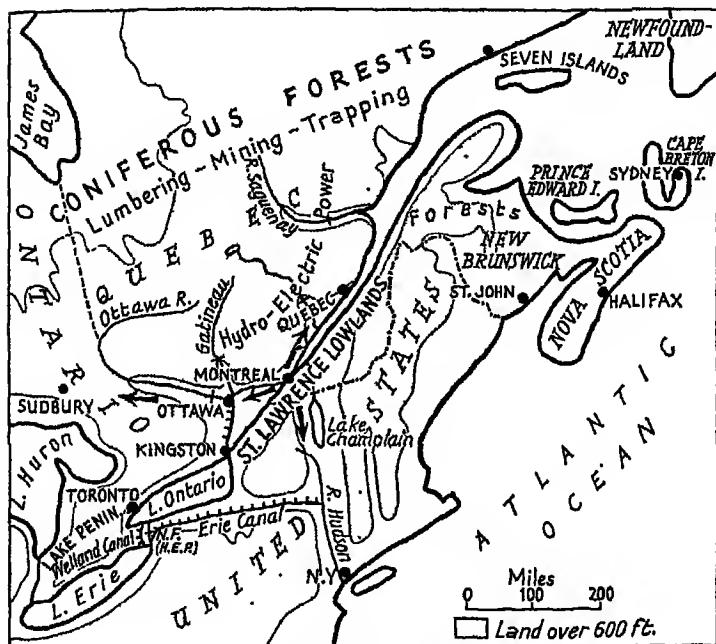

FIG. 238. Eastern Canada.

as well as tobacco, which is grown along the shores of Lake Erie.

Canadian manufactures owe their rapid development, since the beginning of the present century, almost entirely to cheap hydro-electric power, to plentiful supplies of raw materials close at hand, and to advantageous shipping facilities to local and world markets. South of the Great Lakes lies the most densely peopled area in the United States, which supplies the St. Lawrence Lowlands with coal, and in return takes agricultural produce, minerals, and newsprint. The above factors, supplemented by adequate rail and road transport, and protective tariffs, have played an outstanding part in transform-

ing the littoral region, stretching from Lake Ontario to Quebec, into one great manufacturing area. Thus it is not surprising that the St. Lawrence Lowlands, comprising little more than one-tenth of Canada, contain over 60 per cent. of the population, and five of the Dominion's largest towns.

Montreal (1,125,000), on an island in the St. Lawrence, about 1,000 miles from the open Atlantic, stands at a point where a number of land routes converge on the river. It is the chief port of Canada, one of the greatest grain-exporting ports in the world, and the principal French-speaking city in the country. It makes machinery, rolling-stock, and clothing, and is the chief centre of Canada's growing aircraft industry. *Ottawa* (222,000), the Dominion capital, is a saw-milling, pulp, and paper-manufacturing city. *Quebec* (180,000), on the left bank of the St. Lawrence, is noted for its paper, cotton, and woollen mills. *Toronto* (670,000), on Lake Ontario, makes agricultural machinery, packs food products, and has engineering works. Since 1959, when the St. Lawrence Seaway was opened for traffic, Toronto has been a port accessible to large ocean-going vessels. *Kingston*, with railway works, and *Hamilton* (240,000), with shipyards, should also benefit by the construction of the St. Lawrence Seaway.

(3) The Coniferous Forest Belt. The greater part of this belt lies within the Canadian Shield, whose old crystalline rocks weather to form scanty infertile soils. This rugged region is a land of extractive industries, rich in timber, minerals, water-power, and fur-bearing animals, but thinly peopled.

Canada's forests cover an area nearly eight times that of the British Isles, about half of which is capable of yielding commercial timber. The trees are mainly coniferous softwoods—black and white spruce, red and white pines, cedar, and balsam fir—though in the south-east of the Shield and in the Maritime Provinces deciduous hardwoods, such as beeches, oaks, and maples, are found. In the forests of Eastern Canada, the first to be exploited, the supply of trees like white pine, suitable for sawn timber, is approaching exhaustion. This is largely due to felling, but also to forest fires, which do incalculable damage. The present timber output of Eastern Canada consists mainly of spruce and balsam fir, whose logs provide excellent material for the pulp and paper industries.

In Eastern Canada the lumbering season is in winter, when the frozen state of the snow-covered ground facilitates transport. Felling lasts from later autumn until the end of the year. Then hauling begins and the logs, piled on sledges drawn by teams of horses, are dragged to banking grounds beside the rivers. When the great 'freeze-up' ends they are floated down the streams to the pulp- and paper-mills. In British Columbia, where there are still magnificent forests, the bulk of the timber goes to saw-mills. In some parts of this province lumbering (here known as logging) is carried on throughout the year, except during exceptionally heavy snowfalls in the depths of winter, and in the height of summer when the danger of forest fires is great.

For centuries hunting animals for furs has been a winter occupation in the forests. Much trapping is still carried on, and there are also fur farms, where animals are reared for their skins. Montreal, Winnipeg, and Edmonton are leading fur markets.

Except for coal, the crystalline rocks of the Canadian Shield are rich in minerals, notably nickel, copper, gold, and silver. The chief copper-nickel mines are at Sudbury, Ont., and, besides copper, they supply half the world's nickel. Canada ranks next to South Africa in her output of gold, much coming from Ontario, where the chief mines are at Timmins and Kirkland Lake. Asbestos is mined at Thetford, P.Q. Uranium is worked in the Blind River area of eastern Ontario. From the huge Quebec-Labrador iron-field, around Knob Lake, ores are sent by rail to the port of Seven Islands, on the St. Lawrence, and there shipped to iron and steel centres on the Great Lakes.

Many of Eastern Canada's saw-, pulp-, and paper-mills, mines and factories could not be profitably worked without the cheap *water power* supplied by harnessing the many falls of the Shield and its margins. The water-power resources of Canada are unsurpassed by those of any country except the United States. The southward flowing rivers of the Shield descend into the St. Lawrence by falls, whose waters are used by power stations on the Ottawa, Gatineau, St. Maurice, and Saguenay Rivers. In the Saguenay valley, besides saw- and pulp-mills, there is a big aluminium plant at Arvida, which uses hydro-electric power to process bauxite from British Guiana. Among the newest power stations are a number on the St. Lawrence Seaway.

(4) **The Prairie Provinces.** From the Red River Valley the treeless, level, or undulating prairies slope gradually upwards towards the Rockies. They consist of three steps rising one above the other by low escarpments. The first, called the Manitoba Lowland, is a level plain with an average elevation of 800 feet. The second, a more undulating region, stretches from Manitoba into Saskatchewan, rising on the west to 1,600 feet. The third step, which has a still more diversified surface, spreads through Alberta to the foot-hills at the base of the Rockies, where it attains an elevation of 3,000 feet.

The heavy black soil, rich in humus, the winter snows, the showers of late spring and early summer coupled with brilliant sunshine, and the relative flatness of the country, which permits the use of large-scale machinery, have made the prairies one of the leading cereal-growing areas in the world. Wheat, oats, and barley are the chief grain crops, and of them all wheat takes pride of place. In Manitoba, the first province to be opened up, mixed has replaced one-crop farming, and the growing of cereals and root crops is now combined with stock-farming and poultry-keeping.

On the prairies ploughing starts soon after the melting snows have moistened the ground. The seeds, sown by means of drills drawn by horses or tractors, are planted in the latter part of April. The ground is then harrowed, a process that tends to lessen evaporation and conserve the moisture in the soil. Growth is rapid. The crops usually head out by the middle of July and are ready for cutting a month later. Self-binders and reapers and still more modern machines called combines are used for harvesting. After the grain is threshed it is taken by wagons or trucks (lorries) to country elevators beside the railways to await dispatch. Much wheat is shipped through Vancouver, e.g. to Japan; and much goes via Winnipeg to Fort William-Port Arthur, whence some is sent by rail to Montreal, but the bulk is shipped by the Great Lakes-St. Lawrence Seaway, and passes through Montreal on its way to the United Kingdom and other European countries. Some wheat is also exported through Churchill, on Hudson Bay.

In those parts of Saskatchewan and Alberta where the rainfall is light, many cattle, horses, and pigs are bred. In Alberta conditions are specially favourable for ranching. This is due to the excellent grazing land among the foot-hills of the Rockies, and to the Chinook winds, caused by air that descends from the Rockies

35. THE CANADIAN SHIELD AND NIAGARA

(Above) The Canadian Shield between the Great Slave and the Great Bear Lakes. The rounded hills, varying in height from 300 to 1,000 feet, are covered with a scanty soil sheet of glacial drift. The hollows are filled with lakes which spill from one another by short streams. In parts, 75 per cent. of this area consists of water. Scanty coniferous forests cover the hills.

(Below) The Niagara Falls as seen from the Canadian side. Photograph by Jasper Stembridge.

36. NATIONAL PARKS IN THE CANADIAN ROCKIES

(Above) Some of the peaks in the mountains surrounding Maligne Lake, in Jasper National Park, which have been named the Queen Elizabeth Ranges to mark the Coronation. This park, with the adjoining park of Banff, covers 6,700 square miles. (Below) Bison in Banff National Park. Photograph by Jasper Stembridge.

37. TWO OF CANADA'S RESOURCES

(Above) A Paper Mill at Three Rivers, Quebec. The pile of pulp-wood on the right has been lifted by a conveyor ready to be transported to the mill when required. (Below) A general view of Trail, B.C., situated on the Columbia River. The chimneys of the huge smelter of the Consolidated Mining and Smelting Company may be seen on the right. The surrounding hillsides are practically devoid of vegetation, but much has been done, in recent years, to abate the injurious effects of fumes from the smelter.

38. THE WHEATLANDS OF CANADA

(Above) Harvesting on the prairies. A grain truck being loaded from a combine which cuts and threshes the wheat. (Below) Immediately after the break-up of ice on the Great Lakes this steamer arrived at Port Arthur-Fort William to load grain at Pool Terminal 7, one of the greatest grain elevators in the world. The grain is pouring down through pipes which can be seen above the ship. Photograph by Jasper Stembridge.

becoming heated in contraction. In autumn these warm dry winds turn the standing grass into 'prairie hay'; in winter they melt the snow, and so make the grass available for stock which are able to remain out of doors at this season.

Alberta has valuable mineral resources. Lignite is mined near Calgary, bituminous coal near the Crow's Nest Pass, and gold at Goldfields on Lake Athabasca. The discovery of oil in the Turner

FIG. 239. Canada: Agriculture on the Prairies.

Valley (1936), near Calgary, and at Leduc-Woodbend, and Redwater (1948), was followed by the laying of pipelines from Edmonton to (a) Vancouver and (b) via Superior, on Lake Superior, to Sarnia, on Lake Huron, where there are oil refineries.

In the prairie provinces the population varies from 1 to 3 persons per square mile, the most thickly peopled belts lying near the railways. *Winnipeg* (255,000), at the confluence of the Red River and the Assiniboine, is one of the foremost wheat centres in the world. It mills flour, makes farming machinery, and cans meat. *Calgary*, commanding the route through the Kicking Horse Pass, is a distributing centre, as, too, are *Regina*, the capital of Saskatchewan, and *Saskatoon*. From *Edmonton*, capital of Alberta, and airport for the North-West and Yukon, a line runs to Waterways, the railhead, on the Clearwater, a few miles from its confluence with the Athabasca.

(5) **The Arctic and Sub-Arctic Region** comprises the highlands of the Yukon, the Mackenzie Valley, and the northern portion of the Canadian Shield, which extends through the North-West Territories into northern Quebec and Labrador. But though this region occupies half of Canada its sole inhabitants are 14,000 whites, 8,500 Eskimos, and about 6,500 Indians. The coniferous forests thin out towards the Arctic, where the moss-grown tundra provide grazing for reindeer. The Indians and Eskimos fish, hunt, and trap. But more important than fur-trapping and trading is mining, for the rocks of the Shield are highly mineralized. The chief gold-mining centre is Yellowknife, on the Great Slave Lake, the scene of the world's first aerial gold-rush (1937), where the mines now obtain electricity from a power plant on the Snare River, opened in 1948. Silver, copper, and pitchblende (radium- and uranium-yielding) ores are mined at Port Radium, on the east side of Great Bear Lake. Steamers ply on the Athabasca and Mackenzie Rivers during summer, but the chief means of transport is by air. Planes, based on Edmonton, serve Dawson and Whitehorse, in the Yukon, Yellowknife and Port Radium, and settlements in the Mackenzie Valley, including Norman Wells (mineral oil). Highways are slowly being pushed north. The Alaska Highway, constructed during the last war, runs from British Columbia through the Yukon to Alaska (see p. 431).

In the Eastern Arctic huge deposits of iron ore are now being opened up on the borders of Quebec and Labrador (see p. 407).

(6) **British Columbia.** The fiorded coast of British Columbia is separated from the open Pacific by an island-fringe. Between the ranges of the Western Cordilleras lie plateaux and upland valleys, above which jagged peaks tower over glaciers and snow-fields. The prevailing south-west winds cause a heavy rainfall along the seaward slopes of the ranges, but the interior plateaux and valleys are drier, though plentifully supplied with water, for they are irrigated by snow-fed streams. We may divide British Columbia into two regions: (a) the Rocky Mountains and (b) the Pacific Fiorded Coast Region.

(a) In the *Rocky Mountains* lumbering and mining are the main occupations, though farming is carried on in valleys, like those of the Okanagan and Kootenay districts, which are famed for their apples. Magnificent forests clothe the lower slopes of the mountains. At

lower levels grow Douglas firs, Sitka spruces, and other gigantic conifers yielding valuable timber, but the smaller trees found at higher elevations are only fit for pulpwood. Rivers provide transport for logs and power for electricity, but in many districts, owing to the rapidity of the streams, timber is hauled by light railways, or motor tractors. In numerous areas lumbering continues throughout the year.

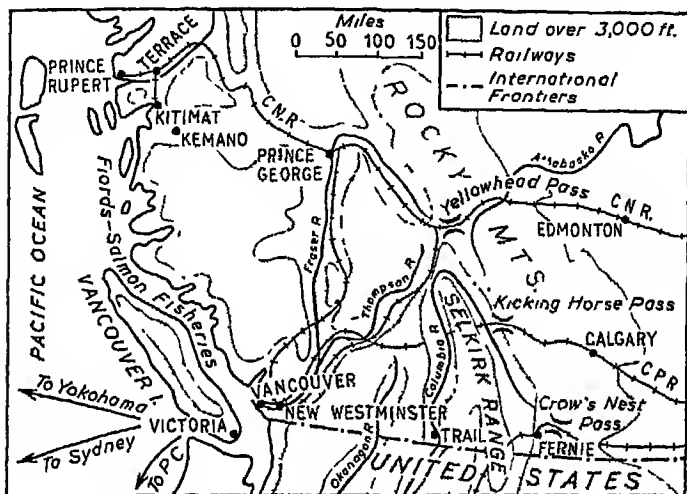

FIG. 240. British Columbia: Routes across the Rockies.

British Columbia ranks after Ontario as the chief mining province of Canada. Coal is worked near Fernie, west of the Crow's Nest Pass, and also near Nanaimo, on the south-east coast of Vancouver Island. Copper is mined at Britannia Beach on the Pacific coast, and, with lead and zinc, in the Kootenay district. The ores are concentrated locally, and then sent to Trail, where there are smelters, refineries, and metallurgical works, supplied with coal from Fernie, and electric power from plants on the Kootenay River. Gold is mined in the north of British Columbia and in the Yukon.

(b) *The Pacific Fiorded Coastal Region.* The salmon fisheries of British Columbia, together with those of Alaska and the north-west of the United States, are the most valuable in the world. Deep-sea

fishing, with Prince Rupert as the centre, is important. South of Prince Rupert, a huge smelter at Kitimat uses hydro-electric power, and alumina from Jamaica, to manufacture aluminium.

The majority of the people of British Columbia live in the few towns, most of which are ports. Communication between the towns and fishing villages is carried on by steamer, for there are no railways running along the fiorded coasts, though Vancouver is a terminal port for the Canadian Pacific and the Canadian National Railways. Canada's chief Pacific port, *Vancouver* (665,000), standing on the ice-free harbour of Burrard Inlet to the north of the Fraser delta, exports wheat, timber and petroleum. Like *New Westminster*, a few miles up the Fraser, it has saw- and pulp-mills, and salmon canneries. *Victoria* (125,000), the port-capital of British Columbia, lies in the south-east of Vancouver Island, a well-forested area.

Communications. The *St. Lawrence and the Great Lakes*, the chief inland water-way in the world, link the grain areas of the prairies and the iron-ore district of Minnesota (see p. 418) with the industrial regions of Eastern Canada and the United States. Rapids are avoided by canals. The *Sault, or Soo Canals*, link Lake Superior with Lakes Huron and Michigan; and the Welland Canal by-passes the Niagara River and Falls. The old canals, cut to avoid rapids between Lake Ontario and Montreal, have been replaced by a new series of channels and locks, opened for traffic in 1959. Now big ocean-going ships can travel from the Atlantic up the *St. Lawrence Seaway*, as it is called, right through to ports on the Great Lakes, such as Toronto and Chicago. Unfortunately the *St. Lawrence-Great Lakes* water-way is closed by ice in winter, while fogs in the Gulf of St. Lawrence sometimes hinder shipping.

There are 42,000 miles of railway in Canada. Two transcontinental lines, with many branches, link Eastern Canada with the Pacific, the east to west journey taking about five days. The *Canadian Pacific Railway (C.P.R.)* runs from St. John (N.B.) through Montreal to Ottawa. Thence it passes through Port Arthur-Fort William to Winnipeg, and after traversing the southern prairies, crosses the Rockies by the Kicking Horse Pass, and descends by the Thompson and lower Fraser Valleys to Vancouver. The *Canadian National Railway (C.N.R.)* includes within its system a number of formerly independent lines that have been taken over by the government. Its

eastern terminus is Halifax: its Pacific ones, Vancouver and Prince Rupert. In general it follows a more northerly route than the C.P.R. The importance of air transport in a country so vast as Canada can scarcely be overestimated. The Dominion network is linked with that of the United States, and, of course, with trans-Atlantic and trans-Pacific air services.

Trade and Commerce. *Exports.* The exports of Canada fall into four main groups, given here in order of value. (1) Forest products, including wood-pulp, planks, boards, paper, and news-

FOREIGN TRADE OF CANADA			
IMPORTS		EXPORTS	
Machinery	■■■■■	Forest	■■■■■
Motor Cars	■■■■■	Products	■■■■■
Petroleum	■■■■■	Grain & Flour	■■■■■
Coal	■■■■■	Metals	■■■■■

FIG. 241. Canada: Foreign Trade.

print, whose value exceeds that of timber and wood-pulp combined; (2) Food products, including wheat, flour, cheese, fish, and meat; and (3) Metals, exported mainly in semi-manufactured form, e.g. copper and nickel bars, sheet aluminium, etc.

Imports. Among Canada's chief imports are machinery, required both for her expanding industries and for agricultural purposes; cotton goods; aircraft; motor-cars and parts, which tend to show that the Canadians have a high standard of living; coal, obtained mainly from the United States; petroleum, needed to supplement home supplies (see p. 409), imported chiefly from Venezuela; bauxite from British Guiana and Jamaica; and tropical products, such as rubber (Malaya), cane-sugar (the West Indies, Australia, and Fiji), tea (Ceylon and India), and coffee (Brazil).

About two-thirds of Canada's foreign trade is carried on with the United States, which has vast sums of money invested in Canadian industries. There is, however, much trade between Canada and though the balance of trade is greatly in Canada's favour. There is also a growing trade with Japan and West Germany.

EXERCISES

1. Give an account of the St. Lawrence Lowlands, describing their natural resources, industries, and chief towns.
2. Contrast Vancouver and Montreal with respect to (i) climate, (ii) access to hinterland, (iii) position for trade, and (iv) nature of trade.
3. Give an account of the distribution of water-power in Canada, and show its influence on the industries of the Dominion.
4. Show how the commercial development of Canada has been assisted or retarded by (i) relief, (ii) rivers, and (iii) natural vegetation.
5. Write an account of British Columbia under the headings: relief, climate, farming activities, fishing, mining, communications, and towns.
6. Give an account of the distribution of population in Canada, noting the geographical factors that have influenced that distribution.
7. Under the following headings write an account of cereal production in Canada: relief and soils; climate; season and methods of sowing, harrowing, and harvesting; transport to railway and markets.
8. Give an account of the import and export trade of Canada, paying special attention to the trade of the Dominion with (i) the United Kingdom and (ii) the United States.
9. With the help of a sketch-map, briefly describe the types of country you would traverse on the Canadian Pacific Railway between Montreal and Vancouver.
10. State clearly and concisely *three* ways in which the Canadian Prairies and the Canadian Shield differ. Then give reasons for the differences stated.

CHAPTER XXVII

THE UNITED STATES

THE area of the United States, excluding Alaska and her overseas possessions, is almost 3 million square miles. But though the size of the Republic is somewhat less than that of Canada, its population is twelve times as great. Out of 172 million people, the majority are of European descent. Though mainly of British and Irish stock, they include representatives of every country in Europe, more especially of Germany, Poland, Russia, and Italy. There are 18 million Negroes, nearly half a million Indians, residing mainly on reservations, and a number of Japanese and Chinese, found principally along the Pacific seaboard.

The most thickly peopled area is the north-east, partly because of its proximity to the Atlantic seaboard and the Great Lakes, and partly on account of the Pennsylvanian coal-field. The mountain states are the most thinly peopled (see Fig. 252).

Regions of the United States. We may divide the United States into the following regions: (1) the North-East States, which may be subdivided into (a) New England and (b) the Central Appalachians and their margins; (2) the Central Lowlands; (3) the South-East Lowlands; (4) the High Western Plains; (5) the Rocky Mountains and Plateaux; (6) the Pacific States, which may be subdivided into (a) the North-West States (Oregon and Washington), and (b) California (Fig. 242).

(1) **The North-Eastern United States.** (a) *New England.* In its relief, indented coast-line, and climate New England resembles the adjacent Atlantic Provinces of Canada. A rather inhospitable interior led the early settlers to supplement farming by fishing and shipbuilding, for which ample supplies of timber were available. They also made cloth from local wool, first in their homes and later in mills, using direct water-power. These activities led to an accumulation of capital which, coupled with initiative and inherited skill, gave the New England people a lead in the Industrial Revolution.

In the northern states, fishing, farming, and lumbering are still the leading occupations. Boston and Gloucester are leading fishing-centres. *Portland* (Maine), a terminal port of the C.P.R., has a con-

siderable export trade in timber. Mixed farming is the rule. Dairy produce, fruit, and vegetables find ready markets in the urban areas.

The south of New England is largely industrial. The early woollen industries paved the way for cotton manufactures with raw material from the Southern States. Cotton and woollen goods are still manufactured in large quantities, but in recent years

FIG. 242. United States: Chief Regions.

the textile industry has declined in importance. Cotton manufacturing towns include New Bedford and Lowell. Among those producing woollen goods are Providence (R.I.), Springfield, and Worcester. But in most of these centres the numbers employed in textile factories are less than formerly and skilled labour has been diverted to other industries. These industries include the manufacture of light metal goods; electrical and other machinery for which Boston is a noted centre; and aircraft engines made at New Haven, Bridgeport, and Hartford. Shoe-making is carried on at Worcester, around Boston, and at Springfield. The last named town, with others in the Connecticut valley, manufactures paper with imported wood-pulp. *Boston* (800,000) is the chief port, commercial, and distributing centre in New England.

39. SCENES IN THE MISSISSIPPI BASIN

(Above) The Mississippi at New Orleans where levees have been built to protect the city from the river. (Below) Steel Works at Pittsburgh. Note the coking plant with its tall chimneys, the blast furnaces, and beyond them the dumps of coal and (left) limestone.

40 NEW YORK AND THE BOULDER DAM

(Above) New York the tip of Manhattan Island with the Hudson River in the background and the East River in the foreground. Note the skyscrapers (see p 419) (Below) The huge Boulder Dam on the Colorado River, which enables water to be stored for power and irrigation. The power station can be seen on the left (see p 426).

41. THE UNITED STATES—CATTLE COUNTRY AND A CHICAGO STOCKYARD

(Above) Cattle on the High Western Plains stretching along the eastern foothills of the Rockies. These animals will ultimately be sent by rail to be fattened on the lowlands of the Mississippi, whence many will find their way to the stockyards of Chicago (*below*) (see pp. 421 and 425).

42. PETROLEUM AND COTTON

(Above) An Oil Field in Texas. The steel derricks hold the drills used to bore down into the ground for oil, which is piped to refineries (see pp. 421 and 422). (Below) A Cotton Gin. The cotton has passed through a ginning machine, which separates the seeds from the cotton lint. After the seeds have been removed, the lint is pressed into bales, each weighing 500 lb. (see p. 424).

(b) *The Central Appalachian Region* extends from the Atlantic seaboard, across the Appalachians, to Lakes Erie and Huron. A number of routes link the ports and towns of the seaboard with those of the trans-Appalachian section. Of these, the most important is the Hudson-Mohawk Valley, leading northward to the St. Lawrence and westward to the Great Lakes. Other, but more difficult, routes

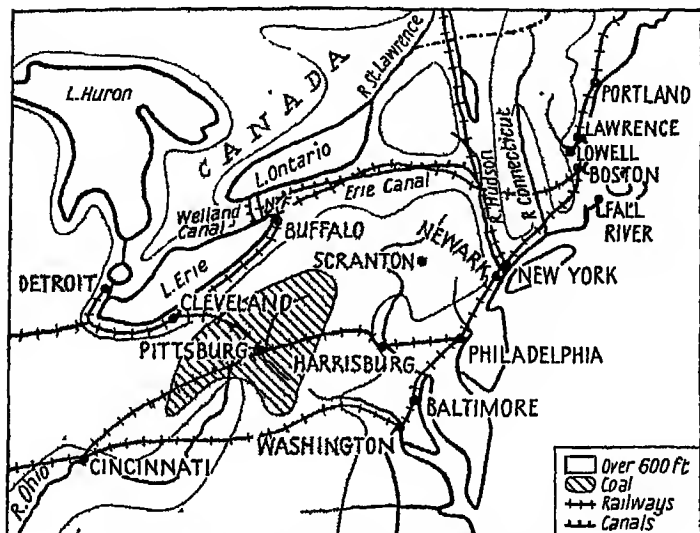

FIG. 243. United States: North-eastern States.

follow the valleys of the Delaware and Susquehanna to the Harrisburg Gap and so to Pittsburg; the Potomac to the Cumberland Gap, and the James river. All are traversed by railways, but with the exception of the Hudson route all are handicapped by very heavy gradients which add to transport costs.

The United States produces about one-third of the world's *coal*. Of this amount more than half is obtained from the *Appalachian Coal-field* stretching from northern Pennsylvania along the Appalachians to Alabama. This area includes the *Pennsylvanian* and *West Virginian* fields. As throughout this region the rivers have cut deep valleys into the horizontal coal seams, galleries can be run into the mines from the sides of the valleys, thus making it unnecessary

to sink shafts. Most of the coal is of the bituminous type, which is easily mined by machinery and cokes well. Anthracite is, however, found in North-East Pennsylvania. Though vast amounts of coal are required for the many industries, especially for smelting iron ore, much is exported from Cleveland and other ports on Lake Erie, while

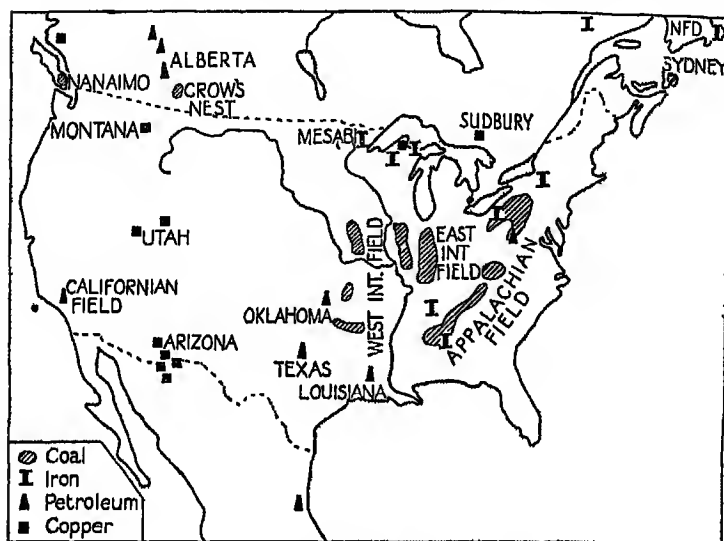

FIG. 244. North America : Distribution of Coal, Iron, Petroleum and Copper.

West Virginian coal is sent by rail to Newport News for export by sea.

The presence, in relative proximity to coal, of iron ore and limestone did much to make the Pennsylvanian area one of the foremost *iron-smelting* districts in the world. Local deposits of iron ore are now almost used up, and supplies come mainly from open-pit mines in the Mesabi Range (100 miles north-west of Duluth), and from the Quebec-Labrador iron-field, the ore from both areas being shipped by the St. Lawrence Seaway (i) to Chicago and Gary on Lake Michigan, where it is smelted with coke from the *Illinois-Indiana Coal-field*; (ii) to *Cleveland* (900,000) and *Buffalo* (580,000) on Lake Erie, whose smelters are supplied with coal from the Pennsylvanian field. From Cleveland much ore is sent by rail to *Pittsburg*

(670,000), which still remains the largest steel centre in a country whose output of pig-iron and steel exceeds that of any other in the world.

New York (7,800,000), situated on Manhattan Island between the Hudson and East Rivers, has a splendid harbour sheltered by Long Island. It owes much of its importance to the fact that the Hudson-Mohawk Valley is the only lowland route from the Atlantic seaboard of the eastern States to the interior. New England and the lowlands to the south are to no small extent tributary to New York, but the great city is linked by the Hudson-Mohawk route with a vast and rich hinterland, which includes the Pennsylvanian industrial area and the region served by the Great Lakes. It is not surprising that with these advantages New York has become the chief port of the United States, its leading banking and commercial and one of its principal manufacturing centres. Its industries are too numerous to specify, but they include the manufacture of clothing, furniture, and tobacco.

Philadelphia (2,000,000) stands at the head of ocean navigation on the Delaware River. As the chief seaport for the Pennsylvanian coal-field, it exports coal and steel, while its close connexion with the coal-field is further emphasized by its foundries, shipyards, and railway works. Petroleum is pumped for hundreds of miles to its oil refineries, and copper is sent from the western mining states, the Keweenaw Peninsula, and also from Chile and Peru (via Panama) to its copper refineries. On the Potomac arm of Chesapeake Bay stands *Washington*, the capital of the United States; on the northern arm of the bay is *Baltimore* (940,000), whose trade and industries are very similar to those of Philadelphia. *Richmond*, on the James River, is an important tobacco market and exporting port.

(2) **The Central Lowlands.** The Central Lowlands, which form part of the great interior plains of North America, lie wholly in the basin of the Mississippi. The primary business of this region is farming. The area as a whole is well wooded and in the north there are still extensive forests. The presence of coal, petroleum, and natural gas, together with water-power, has given rise to a number of industries associated with the forest lands and the farms. Thus, Saginaw and Grand Rapids (Michigan) have both large furniture factories supplied with local and imported timber, and with power derived by harnessing falls.

The chief crops are wheat and maize, but mixed farming is also important.

Wheat is sown both in spring and autumn. The *spring wheat belt*

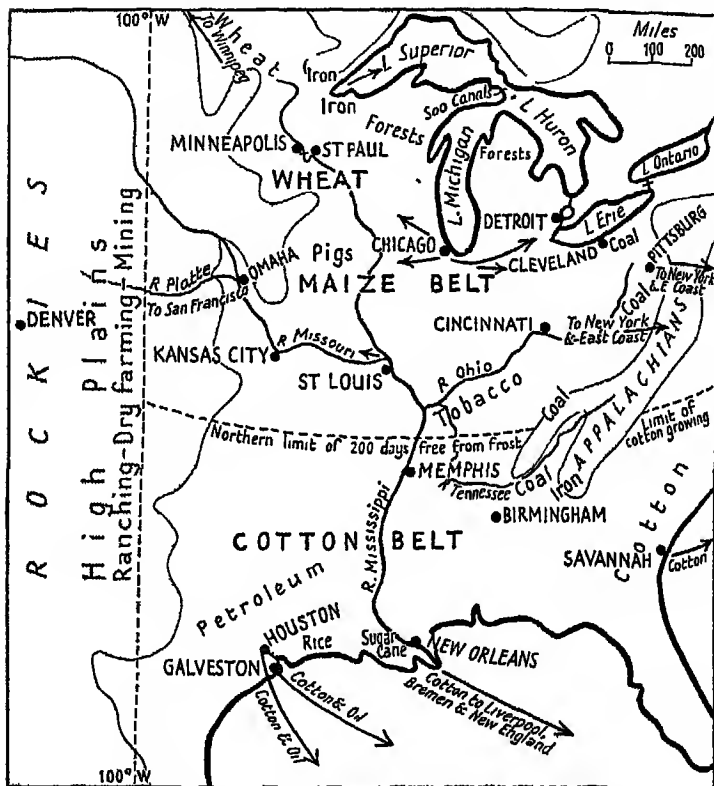

FIG. 245. United States: The Mississippi Basin.

extends from the Middle Mississippi north-west into Manitoba. Flour-milling is carried on throughout the wheat belt, but the chief centres are the twin cities of St. Paul and Minneapolis, whose mills derive their power from the St. Anthony Falls. Oats and barley are also grown in the spring wheat belt, as, too, is flax, produced for its seeds, from which linseed oil is obtained.

On the south the spring wheat merges into the *maize belt*. The winters are less severe than farther north, the springs milder, and the summers hotter and longer, with more rain. Horses, cattle, pigs, and poultry are reared, but of all the crops maize is the chief. In autumn the fields are ploughed, and at the beginning of May the 'corn', as the maize is called in America, is sown. In the middle of August, such portion of the crop as is needed for cattle fodder is cut, and that not immediately required is chopped up and pressed in silos for winter food. The remainder stands until the autumn, when it is harvested, and the kernels husked and dried. Some maize is used for making cornflour, starch, beer, and vegetable oils for soap. Some is fed to poultry, but the bulk is used to fatten cattle and pigs which are sent to the canneries of Chicago, Omaha, Kansas City, St. Louis, and Cincinnati.

In the cooler, moister districts round the Great Lakes much former forest land has been replaced by pasture, devoted mainly to dairying: milk, butter, and cheese all finding a ready market in the densely peopled urban areas.

In the region south of the maize belt proper, *winter wheat*, as well as maize, is grown. It has a higher yield than spring wheat. Sown in autumn, it reaches a height of a few inches before winter. In spring growth is rapid, the wheat ripening towards the end of June.

There are a number of *coal-fields* in the Central Lowlands yielding a rather low-grade coal. Chief among them are: the *North Michigan* coal-field, whose port *Detroit* is noted for its motor-car factories; the *Eastern Interior* field, extending through Illinois, Indiana, and Kentucky; and the *Western Interior* field, stretching from Iowa south to Texas. To these must be added the *Alabama* field, on the southern edge of the Appalachians, where the presence of coal, iron, and limestone has given rise to the iron and steel industries of Birmingham.

About one-third of the world's *petroleum* comes from the United States, much being obtained from the Interior Lowlands, where the chief fields, in order of importance, are those of Texas, Oklahoma, Louisiana, and Arkansas. Outside this region, the leading field is that of California, whose output ranks next to that of Texas. From the wells oil is piped to refineries at ports, or at places right on the oil-fields, such as Dallas (Texas).

Chicago (3,600,000), standing where east to west routes across the

lowlands pass round the southern end of Lake Michigan, is a focus of railway routes. The chief port and leading market for the grain belts, it is a flour-milling and meat-canning centre. In relatively close proximity to coal, and conveniently situated for obtaining iron ore by water (from the Mesabi Range, &c.), it is a great iron and steel centre; while its nearness to a forested area has led to the establishment of saw-, pulp-, and paper-mills. Cincinnati, on the Ohio,

FIG. 246. United States: Oil Fields.

another meat-packing centre, makes agricultural machinery, pottery (local clay), and machine-tools. *St. Louis* (850,000) stands at the confluence of the Mississippi, Missouri, and Illinois. Placed in a farming area, midway between the industrial districts to the east and the ranching lands to the west, and within easy reach of the cotton belt, it is a great cattle and cotton market, a flour-milling, tobacco, and boot and shoe manufacturing centre.

Their rich agricultural and mineral resources and gentle relief, which facilitates transport, have combined to give the Central Lowlands a varied economic life, and have played no small part in stimulating that independent spirit so typical of the people of this region, aptly termed 'The Middle West'.

(3) **The South-Eastern Lowlands.** South of the Ohio valley, the Central Plains merge into the South-East Lowlands, which extend to the Gulf of Mexico. They comprise (a) the *Lower Mississippi*

valley, which passes into (b) the *Gulf Lowlands* and the *Peninsula of Florida*, and (c) the southern portion of the *Atlantic Coast Plain*. Apart from the Appalachians, which project into the lowlands, the relief is flat or gently undulating.

(a) *The Lower Mississippi Valley*. Suitable conditions of soil, and warm sunny summers with ample rain, together with 200 frost-free days,

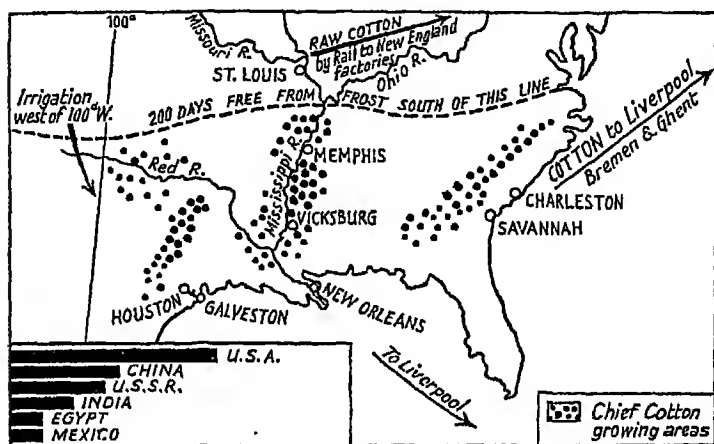

FIG. 247. United States: The Cotton Belt.
Inset: Principal Producers.

have made the lower Mississippi valley and its margins so well adapted to *cotton* growing that this region produces 25 per cent. of the world's supply. North of Cairo, at the confluence of the Mississippi and the Ohio, the warm season is not long enough for successful cotton cultivation; west of longitude 100° W. the annual rainfall is less than 23 inches, the minimum for cotton-growing without irrigation. To the south, the lowlands bordering the Gulf are unsuitable for cotton, mainly because rains fall in autumn when the crop is being harvested. The soils of the cotton belt vary from sandy and sandy or clayey loams to rich dark clays. There are certain districts which, owing to specially favourable conditions of soil and relief, are most productive. The chief of these are the flood plain of the Mississippi, the 'black waxy' prairies of Texas, and the prairies stretching from the Mississippi valley into Alabama, and thence

along the inner margin of the Atlantic coast plain to Virginia. Considerable damage is often done to the cotton crop by the boll-weevil, the larva of a beetle which attacks the boll of the plant.

Though the acreage under cotton has declined recently, cotton is still the chief crop of the South. In some districts it gives way to maize. In others cotton has been replaced by crops, such as soya beans or ground-nuts, or by pasture for beef cattle.

Cotton is sown in February or early March in the south, and as late as the end of April in the north. Picking commences at the end of August and lasts into the autumn, for the bolls, or pods, do not all ripen at the same time. Cotton picking is becoming increasingly mechanized, but the Negro workers still pick much by hand. The cotton is ginned and packed in bales.

The crop is transported by rail to the inland markets and ports. Among the former is Memphis, standing on a bluff overlooking the Mississippi. *Houston*, connected with the sea by a ship canal, and *Galveston*, both in Texas, are the leading cotton exporting ports, followed by New Orleans and Savannah. Galveston and Houston are the chief oil-refining and exporting ports on the Gulf coast. *New Orleans*, at the head of the Mississippi delta, also exports grain, while its imports include bananas, sisal, and petroleum from the Caribbean region, and coffee from Brazil.

(b) and (c) *The Gulf and Atlantic South Coast Lowlands and Florida*. In recent decades cotton manufacturing has greatly increased in the South Atlantic States, notably at the Fall Line towns of *Montgomery*, *Columbia*, and *Augusta*, whose products are coarser and heavier than those of New England. Cheap hydro-electric power has stimulated other manufactures at the Fall Line towns, though a number of factories still use coal. Timber from the Appalachians and coastlands is made into furniture at *Macon*. *Columbus* manufactures agricultural machinery, using iron and steel from the Birmingham district. *Raleigh*, like Richmond, is noted for its tobacco factories, for Virginia and the Carolinas, like the trans-Appalachian state of Kentucky, are famous tobacco-growing areas.

Along the Gulf coast stretches of marshy land are planted with rice, and on slightly higher and better drained ground somewhat farther inland are fields of sugar-cane.

The forests of Florida yield valuable yellow pine, and palms, and fruits like bananas, oranges, and grape-fruits, testify to the warm

climate, as do numerous winter bathing resorts, such as Palm Beach and Miami. All along the South Atlantic seaboard, from Florida to Virginia, are truck farms (market gardens) growing vegetables and soft fruits for the markets of the north-eastern States.

FIG. 248. United States: Florida and the Atlantic Coast Plain.

(4) **The High Western Plains.** Towards the west the Mississippi Lowlands rise to the High Plains, which near the Rockies attain an elevation of from 5,000 to 6,000 feet, and whose average width is 500 miles. The region stretching from Northern Texas into Canada is called the 'dust-bowl' (p. 426). Owing to the low rainfall, the vegetation consists mainly of tufts of grass and sage-bush. The pasture is too poor to support more than a few animals per acre. Store cattle are grazed in the east; sheep in the even drier west. In autumn the cattle are sent by rail to the meat-packing plants at Kansas City and Omaha, or farther east to be fattened in the maize belt.

In this arid region, cereals and forage crops, like alfalfa, are grown by *dry-farming* methods, which aim at conserving the moisture in the soil. The ground is ploughed in early summer and left fallow until the following spring. It is frequently harrowed to keep the top soil loose. This serves a dual purpose. It prevents that hard crust forming after rain, which causes water to be drawn to the surface by capillary action; and it prevents grasses springing up and so using moisture. Crops are sown every other year and thus have the benefit of two years' rainfall. The ground must be as well cultivated when fallow as when planted. Dry farming permits the utilization of semi-arid land, but often such land is unsuitable, and in parts of the 'dust-bowl' the soil has been carried away by the wind, with calamitous results.

(5) **The Rocky Mountains and Plateaux.** Between the main chain of the Rockies and the Cascade and Sierra Nevada Mountains to the west lie a number of plateaux, including the Columbia Plateau; the Great Basin of Inland Drainage around the Great Salt Lake; and the Colorado Plateau, crossed by the Colorado river, whose famous canyon, cut deep into the soft horizontal strata, is 200 miles long, from 4 to 12 miles wide, and over a mile deep.

Shut off by mountain barriers from moisture-laden winds, the whole region receives a scanty rainfall. There is some grazing, but much of the land is desert. Yet the soil is potentially fertile. In recent decades more than 125 dams have been built across the rivers to store water for irrigation and power, and, incidentally, to aid flood control. Among the greatest are the Boulder Dam, on the Colorado River, and the Grand Coulee Dam built across the Columbia River (p. 390). The latter dam, which began operating in 1941, will ultimately provide water for irrigating a million acres, and power for the world's greatest hydro-electric generating units. Lake Roosevelt, the reservoir formed by the Grand Coulee Dam, extends for 151 miles to the Canadian frontier, south of Trail.

But the chief wealth of this region lies in its *minerals*. The United States is the leading country for the production of copper, lead, and zinc; ranks second to Mexico in the output of silver; and with Canada accounts for about one-quarter of the world's gold. The bulk of the United States' share of these minerals comes from mines in the western mountain states. Arizona, Utah, and Montana lead in copper production, followed by Michigan (Keweenaw Peninsula).

Utah and Montana yield most silver; and Colorado comes next to California in her output of gold. The principal smelting-centre, to which ores are sent from all parts of the western states, is *Denver* (412,000). Another smelting centre is *Bingham* (Utah), which rivals *Butte* (Montana) in its output of copper.

(6) **The Pacific Lands.** Between the Coast Range, on the west, and the Cascade and Sierra Nevada Mountains, on the east, are two valleys separated by a belt of high ground. The more northerly is the Great Pacific Valley or the Puget Trough; the more southerly is the Central Valley of California. The climate of the Great Pacific Valley resembles the adjacent portion of British Columbia, but the Central Valley of California, both in climate and products, resembles the Mediterranean Lands.

The submerged northern portion of the **Great Pacific Valley** forms Puget Sound, and the southern portion is drained by the Willamette, a left-bank tributary of the Columbia. The climate favours dairying and the growth of cool temperate fruits and cereals. The lower slopes of the mountains are clad with forests of Douglas fir and red cedar, whose timbers are floated down the Columbia and other streams to the saw-mills. Many salmon are caught in Puget Sound and the Columbia River. *Seattle*, on Puget Sound, does much trade with Alaska; and like *Tacoma*, a little farther up the Sound, and *Portland* (Oregon), on the Columbia River, carries on considerable commerce with the Far East, exporting raw cotton and copper, and importing tea, rice, and raw silk.

California. The Great Valley of California is drained by the Sacramento and the San Joaquin, which receive tributaries from the Sierra Nevada across which dams have been built to store water for irrigation and power.

The mild winters with short showers and spells of sunshine, and the hot, rainless and brilliantly sunny summers, favour the cultivation on irrigated lands of citrus fruits, widely grown around Los Angeles, and, together with apricots, peaches, and grapes for wine and raisins (Fresno), in the Great Valley. In the south of the Valley, cotton is now so successfully grown under irrigation that California ranks second only to Texas as a cotton-producer. Apples, pears, and plums do well in the coastal belt, while around San

Francisco Bay thousands of acres are devoted to truck farming.

Ample supplies of water-power and petroleum more than compensate for lack of coal. From the main petroleum field, in the south-

FIG. 249. California.

west, oil is pumped to Los Angeles, San Francisco, and Monterey. Sacramento is the capital of California, but far more important is *San Francisco* (760,000), on a magnificent harbour, a focus of sea, rail, and air routes. It builds ships, packs meat, and cans fruit and vegetables. *Los Angeles* (2,250,000), the third city in the United States, is best known as the chief centre of the cinematograph industry. The variety of scenery within easy reach of the city, coupled with the wonderful climate, helped to establish the industry here. It is a great oil refining centre, builds aircraft, and manufactures tyres and textiles. Its port is San Pedro.

Communications. In pioneer days rivers were of great importance in the development of the United States, for overland transport was very expensive. To-day steamers on the St. Lawrence Seaway carry vast quantities of

iron ore, coal, and grain, but otherwise water-borne trade is negligible. Even though the Erie Canal was deepened in 1918 (when it was renamed the Erie Barge Canal) traffic on it is still small. Most of the earlier railways were built to supplement the waterways, but their development marked the decline of river traffic. To-day railways are suffering to some extent from the competition

of motor traffic, and to an even greater extent from air traffic. There are over 256,000 miles of railroad in the United States. This mileage is equal to that of Europe, is five times that of Canada, and comprises somewhat more than 40 per cent. of the world's total. The freight carried, which consists mainly of coal, timber, ores, grain, and cotton, exceeds in bulk that of all other

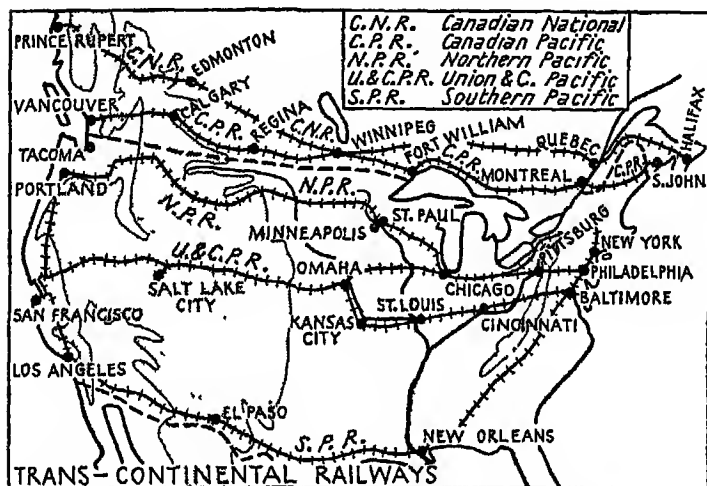

FIG. 250. North America: Transcontinental Railways.

countries combined. Traffic is heaviest in the north-east, the chief industrial and most densely peopled area.

In spite of its enormous mileage, the United States Railway System is, in essentials, fairly simple. Though there are many lines whose general direction is from north to south, yet of greater importance are the west to east transcontinental routes which carry the products of the Pacific States, and of the Central Plains, to the thickly peopled north-east region and the Atlantic ports. These trunk lines are based on the ports, and on certain great inland centres. The chief ports are Boston, New York, Philadelphia, and Baltimore on the Atlantic; New Orleans on the Mississippi; and Seattle and San Francisco on the Pacific seaboard. The great inland railway centres are Chicago; St. Louis and St. Paul on the Mississippi; and Kansas City. From these

and other junctions the main transcontinental lines connect with others to all parts of the Interior Lowlands.

In the Mississippi Plains railway construction was relatively easy: in the Appalachians and Rockies it was difficult, and railways, wherever possible, took advantage of the river valleys. In few other countries is the influence of configuration on railway construction so clearly

FOREIGN TRADE OF THE UNITED STATES			
EXPORTS:		IMPORTS:	
Machinery		Ores & Metals	
		Petroleum etc.	
Grain & Flour		Coffee	
Motor Vehicles		Wood Pulp & Paper	
Raw Cotton		Cane Sugar	
Petroleum		Raw Rubber	

FOREIGN TRADE OF THE UNITED STATES			
EXPORTS TO:		IMPORTS FROM:	
Canada		Canada	
		Brazil	
United Kingdom		United Kingdom	
Japan		Venezuela	
Germany, West		Japan	
Mexico		Philippines	
Venezuela		Colombia	
France		Mexico	

FIG. 251. Foreign Trade of United States.

seen as in the United States. Some of the principal lines are shown on the map (Fig. 250). Study them carefully with the aid of your atlas.

The amount of *air traffic* in the United States exceeds the total of all other countries combined. Cities in the United States are linked by air with others in all parts of the world. Here we may note that the most direct route between places on the west coast of North America and those in western Europe is the Great Circle Route which passes over the North Polar Region.

Trade and Commerce. As the United States is an agricultural and an industrial country both primary and secondary products figure in her *export* trade. Before the last war little grain was exported, but now, owing to a much increased output, grain and flour are among the principal primary exports. Others are raw cotton and tobacco. Such primary products as timber, coal, and iron are to a great extent absorbed by American industry, and petroleum is, on balance, an import rather than an export. The leading manufactured exports are machinery and iron and steel goods, motor

vehicles and aircraft. Among her *chief imports* are wood pulp and paper (mainly newsprint), obtained chiefly from Canada; coffee from Brazil, cane-sugar from the Caribbean lands, wool from Australia, and oil from Venezuela. Natural rubber comes from Malaya and Indonsia, but the demand is lessened because the United States relies partly on synthetic rubber of which she is the world's chief producer.

The *exports* of the United States are of much greater value than her imports. Her foreign trade with Canada exceeds that with any other country. Next in importance is the United Kingdom, her exports to this country being three times as valuable as the goods she imports from it. Other large markets for American goods are provided by Germany, France and Italy; Japan and India; and Mexico, Venezuela, and Brazil.

Outlying Territories. In the Pacific the chief possessions of the United States include the Hawaiian Islands, some of the Samoan Islands, and isolated islands like Midway, Wake, and Guam used as naval, cable, and radio stations, and airports on the trans-Pacific route. In the West Indies, Puerto Rico and the Virgin Islands belong to the United States.

Alaska has an area of somewhat more than half a million square miles. Salmon fishing and lumbering are carried on along its fiorded coast, but the climate of the north is too extreme for trees, and on the tundra Eskimos keep herds of domesticated reindeer, introduced from Russia. There is placer gold-mining on the Yukon River.

Steamer services connect Seattle with Anchorage, the chief Alaskan port. Thence a railway runs to Fairbanks, the terminus of the *Alaska Highway*, which crosses Canada east of the Rockies, and provides road communication between the United States and Alaska. In 1958 Alaska was admitted to full membership of the United States and became the 49th State of the Republic.

EXERCISES

1. (a) Show on a sketch-map the position of the chief cotton-growing area in the United States, and on your map mark three ports of export. (b) Write an account of cotton-growing in the United States under the headings: climate, soils, seasons of sowing and harvesting, labour, transport to home manufacturing areas and to British Isles. (c) In respect of *one* of the chief cotton-manufacturing areas in the United States state the chief factors that have led to the location of the industry in that area.

2 Illustrating your answer by a sketch-map, state *three* ways in which New York fulfils the conditions necessary for a large commercial port

3 (a) Name the chief crop grown in the Agricultural Belt of which St Louis is the centre, and show why this area is specially well adapted for the large-scale production of the crop in question (b) Describe the nature of

FIG 252 North America Distribution of Population.

the outward and inward traffic between St. Louis and (i) the region to the west, and (ii) the Pittsburg industrial area.

4 (a) Using your atlas, show by means of a sketch-map the route followed by *one* transcontinental railway from New York to the Pacific coast (b) Show how the direction of the route you select has been influenced by configuration (c) Describe the chief occupations of the different regions through which the railway passes

5 Give an account of the industries of the following towns, with special reference to the sources of raw material Philadelphia, Cleveland, Cincinnati, and Seattle

6. Select *three* of the following industries film production, furniture making, meat packing, oil refining, and tobacco manufacturing Name *one* centre in the United States important for each of the industries selected, and explain why it has developed there

7 Write notes on dry farming, the Fall Line, the Boulder Dam, and the 'Dust-bowl'

8 Account for the distribution of the population of North America in the region lying between the St. Lawrence—Great Lakes and the Gulf of Mexico

CHAPTER XXVIII

MEXICO AND CENTRAL AMERICA

MEXICO

THE Republic of Mexico, with an area of 767,000 square miles, is about four times the size of Spain. It has a population of 29 millions, of whom about 30 per cent. are of pure Indian blood, some 15 per cent. are of European (mainly Spanish) descent, and the rest are of mixed Indian and Spanish stock.

Mexico consists of (a) a plateau lying between fold ranges, containing active volcanoes, like Popocatepetl; (b) narrow coastal plains; (c) the peninsulas of Lower California and Yucatan. The coastal plains, and the belt below 3,000 feet, form the *Tierra Caliente*. Typical products are mahogany, logwood, bananas (especially near Tampico), sugar-cane, and cotton grown on irrigated lands in the north. The Yucatan Peninsula is noted for henequen, whose fibre (sisal) is exported to the United States for making binder twine and sacks. From 3,000 to 6,000 feet, coffee, tobacco, and maize are cultivated in the *Tierra Templada*. Owing to its elevation (5,000–8,000 feet) the greater part of the Mexican Plateau lies in the *Tierra Fria*, where wheat is grown at lower levels, and forests and upland pastures occur up to 13,500 feet. On the Plateau stands *Mexico City* (2,000,000), the capital, linked by rail with *Vera Cruz*, on the Gulf of Mexico, with *Manzanillo* on the Pacific, and by northern lines with the United States systems.

Minerals account for somewhat over 60 per cent. of Mexico's exports. It is the chief silver-producing region in the world; ranks second for lead; fourth for zinc; sixth for gold and seventh for petroleum. Copper, iron ore, and some low-grade coal are also worked. The oil-fields lie near the Gulf coast. The principal area is between *Tampico* and *Tuxpan*, and a new field has recently been opened up in the south, near Puerto Mexico.

CENTRAL AMERICA

Central America extends from the isthmus of Tehuantepec to that of Panama. It consists mainly of fold-mountains margined by plains on both the Caribbean and Pacific seaboard. As most of Central

America lies in the north-east trade-wind belt, the eastern slopes of the mountains receive the heaviest rain, though the low-lying peninsula of Yucatan (Mexico) is dry.

The northern portion of Central America is politically part of Mexico. The rest of the region is divided into six independent

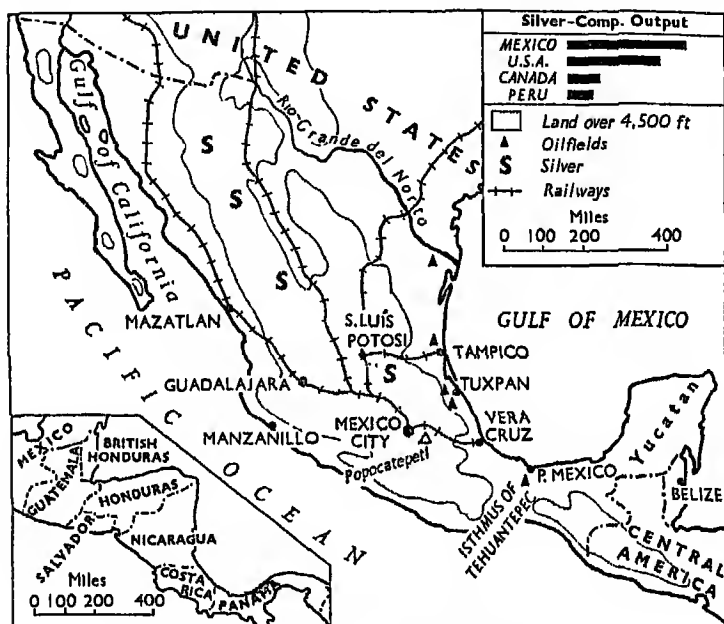

FIG. 253. Mexico and Central America.

republics: *Guatemala, Honduras, Salvador, Nicaragua, Costa Rica*, and *Panama*; and the *British colony of Honduras*, whose capital *Belize* exports mahogany and chiclc, the basis of chewing gum.

The people are mainly of Indian or mixed Spanish and Indian blood. Living in a region somewhat similar to Mexico, they draw the same distinction between the lowland and highland zones as do the Mexicans. The majority live in the *Tierra Templada* and *Tierra Fria* belts. Apart from maize and other foodstuffs grown for home consumption, coffee, for which *Costa Rica* is noted, is the only important cash crop.

The wetter parts of the eastern lowlands are thickly forested, but in recent years large tracts of land near the coast have been opened up for *banana* plantations, most of which belong to United States companies. At the present time Central America and the other Caribbean countries and islands produce more than half the world's bananas. The high temperatures, the heavy rainfall, and the deep alluvial soils provide ideal conditions for the cultivation of this fruit. Bananas are easy to grow, skilled labour is not needed, but where the crop is grown on a commercial scale first-rate organization is essential both in the management of the plantations and in the shipping of the fruit. The plantations are near the coast to facilitate export. As soon as the overseers are informed by wireless of the approach of the fruit ships, the bananas are dispatched to the ports, where they are ready for immediate shipment on the arrival of the vessels. The ships are equipped with every modern facility, including, of course, refrigerating chambers, both for handling and storing the perishable fruit.

FIG. 254. The Panama Canal.

THE PANAMA CANAL

Work on the Panama Canal was commenced by the United States in 1904, and completed in 1914. The length from Colon, on the Atlantic, to Panama, on the Pacific, is 50 miles. The canal is from 300 to 1,000 feet wide, with a minimum depth of 41 feet. Three pairs of locks, near each end of the canal, raise the vessels to the level of the Culebra Cut, across the watershed between the Atlantic and the Pacific. The passage, which takes about 10 hours, enables ships—travelling, for example, between the east and west coast ports of the United States—to save a journey of some 6,000 miles round South America. The canal has caused a great increase in trade between the western seaboard of South America and the North-East industrial area of the United States. Strategically it enables the American

fleet to operate in both the Atlantic and the Pacific Oceans. This vital waterway is defended by powerful naval and air bases. Those guarding the Atlantic approaches extend from Key West, in the Florida Strait, through the West Indies to British Guiana. Sites for bases in British Guiana, St. Lucia, and Antigua, and others in Newfoundland and Bermuda, were leased by Britain to the United States in September 1940. Some months later, the Japanese attack on the American fleet in Pearl Harbour (Hawaiian Islands) precipitated America's entry into the Second World War.

EXERCISES

1. Central America and the countries and islands in and around the Caribbean Sea produce half the world's bananas. Show how the position and the climatic conditions in the Caribbean region are specially favourable for the large-scale production of this crop.

2. In Mexico and Central America the inhabitants draw a sharp distinction between three zones whose climate and produce differ according to their elevation. Name these three zones and show how the climate and products of each are the result of its elevation.

3. Discuss the importance of the Panama Canal with special reference to the United States.

4. Give an account of Mexico, noting its chief physical features, climate, crops, minerals, and people.

CHAPTER XXIX

THE WEST INDIES

STRETCHING like a crescent from the Peninsula of Florida to the delta of the Orinoco, the West Indies form the north-eastern margin of the Caribbean Sea. They may be divided into: (1) *The Greater Antilles*; Cuba, Jamaica, Hispaniola, and Puerto Rico; (2) *The Bahamas* and the *Lesser Antilles*, and (3) Trinidad, which is a detached portion of South America. In the Greater Antilles the mountain ranges run from east to west. The Lesser Antilles are also mountainous, and a number of islands, such as St. Vincent and Martinique, are of volcanic origin and contain active volcanoes. The Bahamas are low coral or limestone islands.

Apart from the Bahamas, the West Indies lie wholly within the Tropics, and so have a tropical climate modified by their maritime position. The annual range of temperature is small, varying from about 70° F. in winter to somewhat over 80° F. in summer. Slight rains fall in winter, but there is a heavy rainfall during the summer months, and seasonal differences depend on rainfall rather than temperature, distinction being drawn between the dry (cool) season and the wet (hot) season. Hurricanes, which occur towards the end of the rainy season, sometimes do considerable damage.

Under these climatic conditions crops can be grown throughout the year. Two West Indian crops—bananas and cane sugar—(see p. 435) are outstanding in world markets. Sugar is widely cultivated, Cuba alone ranking second in world output. The chief factors favouring *cane-sugar* production are: (1) the high temperatures; (2) the heavy annual rainfall, with some months of lesser rainfall before harvest which allows the crops to ripen under the tropical sun; (3) sea breezes; and (4) the alluvial soils. In many districts rocks of volcanic origin weather to form soils rich in such plant foods as lime and potash.

Cuba. The republic of Cuba has an area of about one and a half times that of Scotland, and a population of 6 millions. The people are chiefly of Spanish descent, with a large number of Negroes. Sugar supplies 70 per cent. of the exports, the bulk of which are sent to Eastern Europe. Cuba is also noted for its tobacco. The district

near *Havana*, the capital, produces the leaf used for making the famous cigars. Other products are coffee and sponges.

The island of *Hispaniola* is divided into the two republics of Haiti and Dominica. In *Haiti* the people are mainly Negroes, and the official language is French. Coffee is the most important crop, but sugar, cacao, cotton, and sisal are also grown. The inhabitants of the *Dominican Republic* are of mixed Spanish, Negro, and Indian blood.

FIG. 255. The West Indies and Central America.

Sugar is the chief product, other crops being cacao, tobacco, and coffee. The language is Spanish, but many educated Dominicans speak English.

Puerto Rico is ruled by the United States. The chief crops are sugar, tobacco, and coffee, which are exported to the States from San Juan, the capital. The neighbouring *Virgin Islands* of St. Croix, St. Thomas, and St. John also belong to the United States.

Guadeloupe and *Martinique* are French islands. The chief Dutch islands are *Curaçao* and *Aruba*, whose principal industry is refining oil shipped from the nearby Venezuelan oil-field.

Commonwealth Territories in the West Indies include Jamaica, Trinidad, and the Bahamas, and most of the islands in the Lesser Antilles, among them being Barbuda, Dominica, St.

Lucia, St. Vincent, Barbados, Grenada, and Tobago. In 1958 most of these island-colonies united to form the Federation of the West Indies, but the Federation collapsed when Jamaica, and later Trinidad, withdrew from it to become, in 1962, independent states. The Commonwealth islands, like others in the West Indies, are densely peopled, and most of their inhabitants are of pure or mixed Negro blood.

The *Lesser Antilles* export lime juice, sugar, and cotton.

Jamaica covers 4,410 square miles, and has a population of 1,600,000. The capital is *Kingston*. The chief cash crops are sugar-cane and bananas, shipped mainly to the United Kingdom. Jamaica is the world's largest producer of bauxite, which is exported to the United States, and (as alumina) to Canada.

Trinidad, rather less than half the size of Jamaica, supports 828,000 people, one-ninth living in *Port of Spain*, the capital. Sugar and cacao are exported, but far more important is petroleum. The main oil-wells are in the south-west, where lies the pitch lake of *La Brea* from which asphalt is obtained. *Trinidad* has two big oil refineries. The small island of *Tobago* is administered as part of *Trinidad*.

The Bahamas, a group of islands south-east of Florida, have a land area of 4,400 square miles. They export salt and crawfish. Tourists from the United States and Canada bring much money to the islands. *Nassau* is the capital.

The Bermudas, a group of coral islands in the Atlantic 580 miles east of the coast of Carolina, are famed for their mild climate and scenery, which make them a favourite resort with Americans. Their chief exports are potatoes and green vegetables. Hamilton, the chief town, is less than 4 hours by air from New York. The islands form part of the Commonwealth.

EXERCISES

1. Write an account of the Commonwealth territories in the West Indies and Central America, paying special attention to their exports.
2. What island in the West Indies is especially noted for the production of cane-sugar? Show how climatic conditions favour the large-scale production of this crop in the West Indies.

TEST PAPER : NORTH AMERICA

PART 1

1. Describe the position of *two* important fishing grounds, one off the east and the other off the west coast of North America. In each case, name some of the chief fish caught, describe the methods of fishing, preparing for market, and mention *one* overseas market.

2. Draw a map of Canada to show the main regions into which it may be divided. Which of these regions is the most sparsely, and which the most densely populated? Account for the differences.

3. Draw fully labelled sketch-maps to show : (a) why Chicago is the most important railway junction in the world ; (b) New York is the chief seaport in North America ; and (c) Winnipeg is a great wheat market.

4. How do you account for the following facts : (a) Montreal is icebound in winter, but Halifax is open throughout the year ; (b) Edmonton airport handles more *freight* than any other airport in Canada ; (c) most of the houses in Canada are built of wood ; (d) the younger people living on the prairies are, on the average, taller than those living in the British Isles ?

5. Discuss the Great Lakes as a waterway, mentioning their advantages and disadvantages for transport, and describing their trade and their general importance to Canada and the United States. Give a map.

PART 2

6. Compare the physical features of the Canadian Shield with those of the Western Cordilleras, and explain the more important differences.

7. Select *one* important farming belt in either the United States or Canada. Show how the relief, climate, and soils make it especially well suited to the production of its principal crop. Outline the route by which the crop is dispatched to distant markets.

8. Show how the occupations of the people of Jamaica differ from those of Newfoundland and account for the differences.

9. (a) Name one airport on the eastern seaboard of North America which is a terminal for trans-Atlantic routes, and one on the western seaboard which is a terminal for a trans-Pacific route. (b) Give an account of a journey by air from one of the Atlantic ports to the Pacific port you have named, mentioning four airports of call *en route*, and describing the nature of the country over which you fly. Illustrate your answer by a map.

10. Describe and point out the importance to man of *three* of the following : Boulder Dam, Chinook Winds, Fall Line, Grand Banks, Niagara Falls.

PART VI
SOUTH AMERICA
CHAPTER XXX
GENERAL SURVEY OF SOUTH AMERICA

SIZE, STRUCTURE, RELIEF, AND DRAINAGE

SOUTH AMERICA, which has an area of 7,000,000 square miles, shows marked resemblances in structure and relief to North America. In both we find (1) lofty chains of fold mountains in the west; (2) two masses of much denuded eastern highlands; and (3) central lowlands.

In South America (Fig. 256) the *Andes* extend for 4,500 miles along the Pacific coast, being broadest in the centre, where they are from 400 to 500 miles wide. From the Caribbean Sea three chains, running southwards towards the equator, converge at the Knot of Pasto. Thence an eastern and a western chain enclose the Plateau of Ecuador. In the former chain is the volcano of Chimborazo (20,500 feet), and in the latter that of Cotopaxi (19,600 feet). South of the Gulf of Guayaquil three chains run through Peru to the Cerro de Pasco, near the town of that name. In Bolivia an eastern and a western chain shut in the lofty Plateau of Bolivia, an inland drainage area around Lake Titicaca. South of the Bolivian Plateau the two ranges of the Andes converge southward to culminate in Aconcagua, an extinct volcano 22,800 feet high, the loftiest peak in the continent. Between the Andes and a low coast range lies (in Central Chile) the Vale of Chile. South-west of Aconcagua the Uspallata Pass (12,800 feet) forms a route between Chile and the Argentine. In the south of Chile submergence has taken place and the coast chain is represented by islands, while the Andes themselves consist simply of one main chain. The fiorded coast of this region resembles that of British Columbia.

The Eastern Highlands are divided by the lowlands of the Amazon into (1) the Guiana Highlands, and (2) the Brazilian Highlands. Both masses are composed of old crystalline rocks which, like those of the Labrador Highlands and the Appalachians of North America, have been worn down by prolonged erosion.

FIG. 256. South America: Physical Features.

There are three lowland areas drained respectively by the Orinoco, the Amazon, and the Parana-Paraguay. Though these basins may be regarded as distinct regions, yet the divide between the Amazon and the Orinoco to the north and the Parana-Paraguay to the south is ill defined.

Rivers. Owing to the position of the Andes, all the great rivers of the continent drain into the Atlantic. The Pacific streams are short and swift, but along the coast-lands of Peru their waters are used for irrigation and to some extent for hydro-electric power. The chief rivers flowing into the Atlantic are: (a) the Orinoco (1,500 miles), with its tributaries the Apure and the Meta; (b) the Amazon (4,000 miles), whose headwaters the Marañon, Huallaga, and Ucayali rise in the heart of the Andes, and whose tributaries include the Rio Negro, Madeira, Tapajoz; and the Tocantins which flows into the estuary; (c) the São Francisco, flowing through the Brazilian Highlands; (d) the Plate, into whose estuary run the Uruguay and the Parana-Paraguay.

CLIMATE

In studying the climate of South America certain outstanding factors should be noted. (1) As the greater part of the continent lies within the tropics there is a uniformly high temperature and a heavy annual rainfall over a vast area. (2) As South America steadily decreases in width south of the Tropic of Capricorn, the climate of this temperate area is greatly modified by the vast expanse of ocean that bounds it. (3) Owing to the elevation of the Andes moderate temperatures are found in this region, even in the equatorial belt. As these mountains lie close to the west coast they form, like the Rockies, a marked climatic barrier between east and west.

Temperature (Figs. 257, 258). Nearly the whole of the lowlands of tropical South America have a temperature of 70° F., or over, throughout the year. The annual range is small: at Para, for example, it is only 2.7° F. South of the Tropic of Capricorn oceanic influences tend to moderate the temperature, and there is no marked continental climate as in similar latitudes in North America. The cold Peruvian current, flowing northward along the west coast as far as the equator, has a marked cooling effect in the coastal regions. Thus Iquique, on the west coast, with a summer (January) temperature of 70° F., is no warmer than Bahía Blanca, on the east coast, some 1,200 miles farther from the equator.

The effect of elevation on temperature is well illustrated by Quito, on a plateau in the Andes, 9,350 feet above sea-level. Though practically on the equator, it has a mean temperature of 55° F., with a range of only 0.7° F.

November to April.

FIG. 261. South America: Natural Vegetation.

Rainfall (Figs. 259, 260). The north-east and south-east trade winds, blowing towards the equator, bring heavy rain to the east coast region and even to the leeward slopes of the Andes. This rainfall is increased in many areas by convectional rains, which are also responsible for the rainfall along the west coast north of the equator.

The Guianas and the basin of the Orinoco to the north of the Amazon lowlands, and the Brazilian Highlands to the south, have marked wet and dry seasons, most rain falling soon after the period when the sun is overhead. Uruguay and the southern coasts of the Plate estuary have rain throughout the year, but mostly in summer, the total amount diminishing inland.

Along the west coast, from the equator to about latitude 27° S., the winds blow off-shore or parallel to the coast, which is thus practically rainless, while in the Atacama Desert there is absolute drought. Central Chile (30° S. to 37° S.) has a Mediterranean climate; but Southern Chile, where the prevailing westerlies blow on-shore throughout the year, has rain at all seasons. Note the marked Rain Shadow, on the eastward side of the Andes, south of latitude 37° S.

NATURAL VEGETATION

In South America the relation between rainfall, configuration, and natural vegetation is well marked. *Tropical forests* cover most of the Amazon basin and the low-lying coast-lands of the Guianas, Venezuela, Colombia, and Ecuador. North and south of the Amazon forests, the Guiana and Brazilian Highlands, and the greater part of the Orinoco basin are clad with *savannas*, known as *llanos* in the Orinoco region and as *campos* in Brazil. In the south-west the Brazilian Highlands descend to the lowlands of the upper Parana and Paraguay, where are found the *warm temperate forests* of the *Gran Chaco*. On the other hand, largely owing to elevation, considerable portions of the highlands of South-East Brazil, in similar latitudes, are clothed with *coniferous forests*. Farther south, the *temperate grasslands*, the *pampas*, of the Argentine and Uruguay spread from the Atlantic westward towards the foot-hills of the Andes. In the south of the Argentine, Patagonia is a region of *poor steppe* and *semi-desert*.

The Andes have a typical *mountain vegetation* ranging, in the equatorial belt, from tropical forests to perpetual snow. From the Gulf of Guayaquil southward, the seaward slopes of the Andes grow more and more arid until in the *Atacama Desert* there is practically

FIG. 262. South America: Distribution of Population.
(Number per square mile)

South America has 18 persons to the square mile compared with 21·3 in North America, 19 in Africa, 2·6 in Australia, 77 in Asia, and 145 per square mile in Europe.

no vegetation. Farther south *Mediterranean vegetation*, with ever-green drought-resisting trees and shrubs, is found in Central Chile. In Southern Chile *coniferous* and *deciduous forests* clothe the lower slopes of the rain-drenched Andes.

PEOPLES AND POPULATION

When the Spaniards and Portuguese came to South America, soon after its discovery by Columbus, they found it inhabited by Indian tribes, numbers of whom lived mainly by cultivating manioc and by hunting and fishing, as do many living in the Amazon *selvas* to-day. In contrast to these primitive folk the Incas, whose home was on the uplands of Peru, Bolivia, and Northern Chile, were highly civilized. 'Here on these lofty plateaus were temples, palaces, and fortresses, built of great blocks of stone; well-paved roads; and terraced hillsides, irrigated and planted with maize and potatoes. Poverty was unknown. Life in Cuzco, the capital, was an ever-entertaining spectacle. But the Inca Empire fell before the savage onslaught of the Spaniards. Yet, though the loss of life was terrific, the people were not wholly exterminated, and their descendants, Indians of pure stock, form to-day the majority of the inhabitants of the Peruvian and Bolivian plateaux.'¹

The majority of the inhabitants of South America are of mixed Indian and Spanish or Portuguese blood, the Portuguese being found chiefly in Brazil, once a colony of Portugal. More recent immigrants include Italians and Germans, who are found mainly on the South-East Uplands of Brazil. In the Argentine and Uruguay, which, with Chile, are the only countries having a considerable part of their territories in temperate latitudes, the proportion of people of pure European descent is very high. Many Negroes and folk of mixed Negro origin are found along the north-east coast-lands of Brazil, where the climate is not unlike that of tropical Africa, whence their ancestors came.

In no other continent, except Africa, have climate, relief, and vegetation proved so great an obstacle to settlement as in South America. The population map (Fig. 262) shows that the vast *selvas* of the Amazon arc almost uninhabited, for the dense luxuriant tropical forest is quite unsuited for more than sparse settlement. The arid steppe lands of Patagonia, lying in the rain shadow of the Andes, are

¹ 'America's Republics as a World Influence'; Jasper H. Stenbridge.

another thinly peopled region. On the other hand, it is the rugged topography rather than climatic conditions that hinders settlement in Southern Chile, lying on the windward side of the Andes. In the Atacama Desert settlement is confined to the nitrate and copper-mining centres and the ports through which their products are dispatched. Highland regions, like the Plateau of Bolivia, are thinly peopled, for in these elevated regions life is hard, and only with difficulty do the people wrest a livelihood from the land. Considerable areas of relatively dense population are confined to the south-east coast-lands, and to the more accessible parts of the temperate regions. Chief among the latter are the margins of the south-east Highlands of Brazil, the lowlands of the Plate estuary, and the Vale of Chile.

In the northern countries of South America—Colombia, Ecuador, and Venezuela—most people live in the mountains to avoid the equatorial heat of the lowlands, where settlement is mainly confined to the seaports.

EXERCISES

1. On an outline map of South America (a) insert the Equator and the Tropic of Capricorn; (b) shade that part of the continent which experiences the sun overhead at some time of the year; (c) name and mark by means of arrows showing its direction, *one* cold current and *one* warm current, each flowing near the coasts of South America; (d) insert and name the isotherms 80°F. for (i) July and (ii) January; and (e) print *llanos*, *campos*, and *pampas* each over one appropriate area.

2. Describe and account for the distribution of population in South America south of the Equator.

CHAPTER XXXI

COUNTRIES OF SOUTH AMERICA

COLOMBIA, ECUADOR, AND VENEZUELA

THE North Andean republics of Ecuador, Colombia, and Venezuela lie wholly within the tropics, but as they are traversed by the Andes they contain considerable highland areas. Each has an extensive seaboard, but whereas Ecuador faces the Pacific, and Venezuela the Atlantic, Colombia fronts both of these oceans, and so is best placed for trade with Europe and the United States, on the one hand, and the west coast of the Americas, on the other.

The people recognize the same contrasts between the *Tierra Caliente* and the highland zones as do those of Mexico and Central America. Most of the people live in the ports, or in the more accessible parts of the *Tierra Templada* and the *Tierra Fria*. The coastal lowlands, and valleys such as those of the Magdalena and Cauca, are forested. The *llanos* of the Orinoco extend from Colombia eastward through Venezuela; while the *selvas* of the Amazon stretch from Brazil into each of the three states.

Ecuador. The most productive belt is the Pacific region, where bananas—the main export crop—cacao, rice, and cotton are grown in the *Tierra Caliente*, and coffee in the *Tierra Templada*. The fibres of the toquilla palm are woven by Indian women into Panama hats. From the petroleum field, on the north side of the Gulf of Guayaquil, oil is piped to the coast. *Guayaquil*, the chief port and largest city, at the head of the Gulf of Guayaquil, is the outlet for a fertile valley lying between the Coast Range and the main chain of the Andes. From Guayaquil a railway, 288 miles long, winds up to *Quito*, the capital of Ecuador, situated on the plateau at a height of 9,300 feet above sea-level. The Indian peons living in this region, like their neighbours in Colombia, graze sheep and llamas on the rough pastures, and grow barley and potatoes; but their agricultural methods are primitive, their tools crude, and their crops poor.

Colombia. There are many banana plantations along the Atlantic coast of Colombia, where Puerto Colombia, the outpost of *Barranquilla* (255,000), Santa Marta, and *Cartagena* (115,000) are the chief ports. Cartagena exports petroleum, which is pumped for some 300 miles from fields in the Magdalena valley. *Buenaventura*, the chief

Pacific port, is linked by road with *Bogota* (650,000), the capital, 8,500 feet above sea-level. Cane-sugar and cacao are cultivated in the *Tierra Caliente*; coffee, of which Colombia produces 15 per cent. of the world's total output, in the *Tierra Templada*. The country is

rich in minerals—gold, silver, copper, and manganese—but they are relatively undeveloped. Muso is noted for its emerald mines.

Steamers take 6 days to travel from Barranquilla, up the Magdalena, to Girardot, whence it is a 7-hour railway journey to Bogota; but by air the whole distance can be covered in 3 hours.

Venezuela. Cattle and sheep are bred on the *llanos* of the Orinoco, but owing to poor communications and to floods during the rainy season (May to October) these grasslands are little developed.

Iron is mined south of Bolivar. This port, 270 miles from the mouth of the Orinoco, is a centre of river trade, where goods are transferred to ocean-going vessels for dispatch to Port of Spain (Trinidad) or the Venezuelan ports of La Guaira and Puerto Cabello. From La Guaira a railway and a motor road—one of the few metalled roads in the country—climb some 4,000 feet to *Caracas*, the capital. Though the two towns are only 6 miles apart, the railway is 23 miles long, so many are the spiral curves necessitated by the mountainous nature of the country. *Maracaibo*, on Lake Maracaibo, is the centre of the principal petroleum fields. The petroleum-bearing strata extend under the lake itself and many derricks actually stand in the water. Much oil is piped to refineries in the Paraguana Peninsula, and some is shipped for refining to the Dutch islands of Curaçao and Aruba. There is another large oil-field in eastern Venezuela, a country ranking second as an oil-producer.

THE GUIANAS

The Guiana Highlands are a table-land of which the highest and most extensive portion lies in Venezuela, and not in the three European colonies—British, Dutch, and French Guiana—that bear their name. From the Highlands the Essequibo and shorter rivers flowing to the Atlantic descend by falls, of which the most famous are the Kaieteur Falls on the Potaro, a tributary of the Essequibo, while other streams flow from them to the Orinoco and the Amazon. Rain falls throughout the year, with especially wet seasons in May and June and in December; while in the lowlands temperatures are uniformly high. British, Dutch, and French Guiana may be divided into two Natural Regions: (1) the Highlands and (2) the Lowlands stretching to the Atlantic.

FIG. 266. The Guianas.

(1) Some cattle are reared on the rich but undeveloped savannas of the *Highlands*, where coffee is grown at elevations of from 2,000 to 3,000 feet.

(2) The greater part of the *Lowlands* are clad with tropical forests containing such trees as mahogany; greenheart, from which a hard timber is obtained; balata, yielding rubber; and oil palms near the coast (in French Guiana). On the swampy coastal plains, which in places lie below sea-level, rice and sugar-cane are cultivated, as well as cacao in sheltered and slightly higher districts.

Placer gold is obtained from the rivers, in British Guiana diamonds are won from the streams, and bauxite is found in that country and in Dutch Guiana.

Sugar, rum, rice, and gold are exported from all the *Guianas*. *British Guiana* (capital *Georgetown*) also exports diamonds and bauxite; *Dutch Guiana* (capital *Paramaribo*) coffee; and *French Guiana* (capital *Cayenne*) sends coffee, cacao, and palm oil to Marseilles.

BRAZIL

With an area of $3\frac{1}{2}$ million square miles, Brazil, by far the largest of the South American Republics, is about ninety-two times the size of Portugal, of which she was once a colony. Of her $70\frac{1}{2}$ million inhabitants many are of Portuguese, Spanish, Italian, and other European descent, but the majority are of pure or mixed Indian blood, while others—especially along the east coast—are Negroes or partly of Negro origin. With the exception of the extreme south-east, the whole of Brazil lies within the tropics. More than half consists of the dense *selvas* of the Amazon basin, the remainder comprising the Brazilian Highlands and the Atlantic coast-lands.

The *Amazon*, the longest river in the world, has a larger volume than any other stream, for the greater part of its basin lies within the tropical wet belt. Notice how the Amazon itself flows relatively close to and almost parallel to the equator throughout most of its course. Its headwaters, the Marañon and Ucayali, rise in the Andes within 150 miles of the Pacific. They descend through steep gorges to the densely forested lowlands, which extend, almost at sea-level, to the Atlantic. So flat are they that in the last 2,000 miles of its course the Amazon falls somewhat less than 40 feet. Owing to the flatness of its bed and to its volume the river frequently divides into numerous channels (*igrapes*). It enters the Atlantic through a huge delta whose many distributaries form numerous islands, of which the largest is Marajo. The Para Channel, south of Marajo, is the one mainly used by shipping.

Almost 90 per cent. of the people of Brazil live on the eastern margin of the highlands, or in the ports along the coastal lowlands

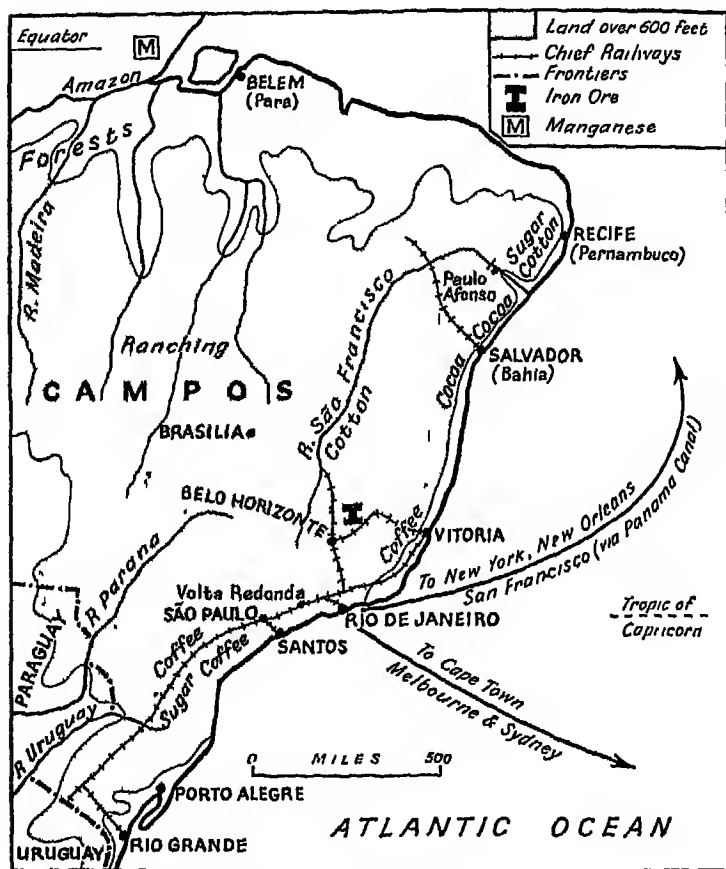

FIG. 268. South-eastern Brazil.

at their base. With an average elevation of from 2,000 to 4,000 feet, the *campos* have a temperate climate, with summer rains typical of such savanna regions. Much ranching is carried on. The chief interior cattle centre is Cuyaba, on the upper Paraguay, but the most

important region is in the more accessible south-east, where cattle are sent by rail to the meat-packing establishments of *Rio Grande*, the chief port, distributing and manufacturing centre of South-East Brazil. *Porto Alegre* is the leading commercial centre in this part of the country.

In the vast pine forests of South-East Brazil, which cover an area

equal to that of France, lumbering is becoming increasingly important. Immense quantities of timber are shipped down the Uruguay river to Uruguay and the Argentine.

By far the most important crop in Brazil is *coffee*, of which the country produces nearly 50 per cent. of the world's output, and which accounts for over 70 per cent. of its exports. The leading coffee growing region extends from the State of São Paulo southward into the State of Parana. Here, at elevations ranging from 2,500 to 5,000 feet, thousands of acres of well-drained hill-sides, exposed to the rain-bearing south-east trades, are planted with coffee trees. The equable climate of these tropical slopes is ideal for this crop,

for the average summer temperature seldom exceeds 70° F., and the winter months are free from frosts, which are fatal to coffee cultivation. The mean annual rainfall is about 55 inches, being heaviest in the summer months from November to February. But above all, it is the deep red soil, formed of weathered volcanic rocks mixed with humus derived from bygone forest trees, that makes this region so suitable for growing coffee. Santos, the chief coffee exporting port, is linked by rail with *São Paulo* (3,150,000), a city

Sawn Timber	

FIG. 271.

that first became important as a coffee market, and is now the biggest city and chief industrial centre in South America.

Brazil grows 15 per cent. of the world's cacao, which crop ranks third in the export list, supplying some 5 per cent. of the total. The chief plantations are found along the sheltered coastal plains stretching from Victoria northward to the mouth of the São Francisco. Much cacao is exported from *Salvador* (Bahia) to the United States. Oranges, of which the bulk are sent to the British Isles, are grown round Santos and Rio de Janeiro, while tobacco is cultivated in the lower São Francisco valley. There are cane-sugar plantations round *Recife* in Pernambuco State, and cotton is grown there and in São Paulo State, where there are many cotton mills.

At one time Brazil was noted for diamonds and gold, but now its chief mineral wealth lies in its rich deposits of *iron ore* and *manganese*, a metal essential to the production of most steels. The principal iron mines are in the State of Minas Geraes. Manganese is worked in the south-west of the Matto Grosso Plateau (at Corumba), and there are other large deposits in the Territory of Amapa, north of the Amazon estuary. The great iron and steel plant at Volta Redonda (north-west of Rio de Janeiro) commenced production in 1948. Brazil lacks high grade coal, but her potential supplies of hydro-electric power are the fourth largest of any country in the world.

Electric power, derived from mountain streams in the south-east, is used in cotton, boot and shoe, tobacco, and match factories at a number of towns along the south-east coastlands. *Rio de Janeiro* (2,900,000) is the Federal capital, but a new capital, *Brasília*, is now being built in the interior. Standing on a fine harbour, Rio de Janeiro has good rail communications with its hinterland. By air it is distant 5 hours from Buenos Aires, 24 from New York, and 24 from Lisbon, via Dakar (Senegal: Africa). More than two-thirds of the foreign trade of Brazil passes through Rio de Janeiro and Santos. The character of the climate is well illustrated by the exports, of which the bulk are tropical plantation products. Frozen meat and other animal produce, obtained from the ranches of the *campos*, figure in the export list, but they are not relatively so important as they are in the Argentine and Uruguay, where they hold the predominant position. Moreover, Brazil imports wheat and other cereals, while Argentina exports vast quantities of grain. Other imports of Brazil are petroleum and motor vehicles. Owing to the growth of her iron and steel industry, Brazil is no longer so dependent on imported iron and steel goods.

THE ARGENTINE REPUBLIC

Argentina has an area of somewhat over one million square miles and a population of nearly 21 millions. Thus it is about a third the size of Brazil with approximately one-third of the inhabitants, but compared with the latter country a much greater proportion of the Republic is productive. The greater part of Argentina lies within the temperate zone, and this, coupled with the fact that the majority of the people are of European descent, has tended to make the inhabitants energetic. Argentina has, however, little coal or mineral wealth. The supplies of petroleum obtained from the Chubut Oil Field (Patagonia) are relatively small, and the development of hydro-electric power in the Andean region is greatly handicapped by its distance from present and potential consuming centres. Thus, though some manufacturing has risen up under the protection of tariff walls, the Argentine is likely to remain for a long time a primary producing country.

Four main natural regions may be distinguished: (1) the Eastern Slopes of the Andes; (2) the Pampas; (3) Patagonia, and (4) the Gran Chaco.

FIG. 272. Argentina, Uruguay, and Paraguay.

(1) **The Eastern Slopes of the Andes** receive little rain. The higher slopes are arid, but in the lower valleys crops are grown on lands irrigated from snow-fed streams. Extensive irrigation schemes, carried out in the Tucuman district, have enabled a considerable area to be devoted to the growing of sugar-cane, which is refined at *Tucuman* (245,000), the provincial capital, and other centres. Another important irrigated area lies round *Mendoza*, on the Transandine Railway. The greater part of this district resembles one huge vineyard, from whose grapes is made most of the wine of the Republic.

(2) **The Pampas**, covering about one-fifth of the country, are the most productive region. Their surface, composed of alluvial and wind-borne soil, is devoid of rocks and stones; and their dead level is broken only by clumps of poplars and eucalyptus trees surrounding ranchers' homesteads, and by the towers of innumerable steel wind-pumps. There are few rivers, and it is these wind-pumps that supply the power for raising the water necessary for men, stock, crops, and railway engines. Owing to the absence of stone for road-making, the roads are merely broad tracks bounded by wire fences, which in rainy weather are a veritable sea of mud. The level surface of the pampas made the construction of railways comparatively easy, and so facilitated their development. They are used both for long- and short-distance transport. The journey by the Transandine Railway from Buenos Aires to Valparaiso takes 39 hours. The line crosses the Andes by a tunnel under the Uspallata Pass, 2 miles long and 2 miles above sea-level. Of the many railways crossing the pampas, one runs from Buenos Aires north-west to Tucuman and Salta, thence connecting with the Bolivian system.

Little more than half a century ago the pampas were a sparsely peopled region inhabited by Indian and half-breed tribes. To-day, thanks to the introduction of pedigree stock to improve the herds, barbed-wire fences, wind-pumps, modern agricultural machinery, railways, and fast steamers with cold-storage facilities, these vast grass-lands have become one of the richest farming areas in the world.

Cattle are widely grazed throughout the pampas, but the chief stock-rearing area is in the south-east of the province of Buenos Aires, where an enormous number of beef and many dairy cattle are bred. Much of the land is sown with alfalfa, whose long roots, which enable it to draw water from a considerable depth, make it more

luxuriant than ordinary grass, thus causing cattle fed on it to be brought to prime condition sooner than otherwise would be the case. Another important cattle-rearing district lies round *Cordoba* (510,000), near the foothills of the Andes. Sheep are widely grazed on the pampas and in Patagonia, but one-third of the 50 million sheep in the Republic are found in Buenos Aires province. Frozen and chilled beef and mutton, live cattle, wool, hides and tallow, butter and cheese are among the principal exports of the Argentine, but as a rule the total value of animal products is somewhat less than that of agricultural products like grain, flour, and linseed.

Wheat is the chief cereal crop, but maize, oats, barley, and flax

FOREIGN TRADE OF ARGENTINA			
EXPORTS		IMPORTS	
CEREALS		MACHINERY	
MEAT		FUEL OILS	
WOOL		TEXTILES	

FIG. 273.

are also grown. The wheat belt forms a crescent, convex towards the west, stretching from Bahia Blanca northward for some 700 miles. The maize belt forms a smaller area within this crescent, with its centre at *Rosario* (500,000), a grain-exporting port at the head of ocean navigation on the Parana. In the southern part of the *Entre Rios*, as the district between the Parana and Uruguay is known, much flax (for linseed) is grown.

Buenos Aires (4,500,000), the capital and chief port of the Argentine and the largest city in the Southern Hemisphere, is the focus of the country's 27,800 miles of railway, and the eastern terminus of the Transandine line to Valparaiso. Through this port passes the bulk of the Republic's overseas trade. *La Plata* (410,000), a meat-canning centre, is a grain- and meat-exporting port; and *Bahia Blanca* (110,000) exports wool and grain.

(3) **Patagonia.** Millions of sheep are bred on the Patagonian Plateau, but owing to the low rainfall and the relative poorness of the pastures the number per acre is small. The inhabitants are mainly shepherds, and in the whole of this region, comprising about one-third of the Republic, there is no large town.

(4) **The Gran Chaco** stretches from the upper Paraguay to the

Andes. The Argentine portion occupies one-fifth of the country. In these vast forests the most valuable tree is the quebracho, the 'axe-breaker', which, like teak, grows in single stands. Its bark yields tannin, used in tanning leather. In the north-east of the Chaco, and in the adjacent areas in Paraguay and Uruguay, yerba maté, or Paraguayan tea, grows both in the wild and cultivated state.

URUGUAY

Uruguay, the smallest of the South American Republics, has a population approaching 3 millions, mainly of Spanish and Italian descent. The Republic stretches from the Atlantic to the river Uruguay, which, with the Plate estuary, separates it from the Argentine. Uruguay consists almost entirely of rolling, treeless grasslands, which form an eastern expansion of the pampas; and both in climate and natural vegetation the country resembles the province of Buenos Aires. Stock rearing is the main occupation. There are in the Republic some 7 million cattle, 23 million sheep, and over half a million horses. *Fray Bentos* and *Paysandu*, on the Uruguay river, handle meat products. Wool, frozen mutton, beef, meat extracts; fine hides from sheep, and thicker hides from cattle; together with other animal produce, furnish over 80 per cent. of Uruguay's exports. About one-fifth of the land is devoted to mixed farms on which, in addition to stock, crops like maize, wheat, oats, and flax are grown. Vines, apples, and oranges are also cultivated. *Montevideo* (900,000), the capital, stands on the northern side of the shallow Plate estuary. *British and Scandinavian whaling-ships, fishing in Antarctic waters, use its harbour for winter anchorage.*

PARAGUAY

West of the Parana, and bounded partly by the Paraguay river, lies the Republic of Paraguay. Its considerable forests include the eastern portion of the Gran Chaco, from which quebracho and yerba maté are obtained. Much of Paraguay consists of grasslands which are admirably suited for cattle, of which there are some 4 million in the country, though, except in the south, temperatures are too high for sheep. The packing establishments produce beef, corned beef, 'jerky' (beef that is dried and salted), hides, tallow, and other by-products mainly for export. The climate, though rather wet for wheat, is good for maize. Other crops include cane sugar, oranges,

cotton, and tobacco; while some rice is grown, and recently banana plantations have been started. Some iron and copper are mined. One-ninth of the population live in *Asuncion* (206,000), the capital, at the confluence of the Paraguay and the Pilcomayo. The city is well placed for river trade and is a collecting centre for produce, which is shipped down-stream to Buenos Aires, some 950 miles distant.

THE FALKLAND ISLANDS

The Falkland Islands, a British Colony, lie 300 miles east of the Strait of Magellan. From *Port Stanley*, the capital, transport to other settlements is by boat or plane, and there is a monthly steamer service to Montevideo. Sheep farming is the main industry, and wool the chief export. *South Georgia*, another British territory, to the south-east, is a whaling centre and exports whale oil.

CHILE

Lying between the Andes and the Pacific, Chile has an area of about 285,000 square miles, or somewhat more than three times that of Great Britain. Its coast-line extends for 2,800 miles, while its average width is about 100 miles. There are three Natural Regions: (1) Southern Chile, extending from Valdivia southward, where the prevailing on-shore westerlies cause heavy rain throughout the year, especially during the winter months from May to August; (2) the Central Vale of Chile, stretching from latitude 30° S. to 40° S., which in winter lies in the rainy west-wind belt, and in summer in the rainless south-east trade-wind belt; and (3) the Atacama Desert of Northern Chile, which has no rain, for the winds blow off-shore or parallel to the coast throughout the year.

(1) **In Southern Chile** the Andes, though lower than farther north, rise steeply from a sunken coast, indented with fiords and fringed with islands which represent the peaks of a submerged range. As driving gales often sweep along the coast, most of the trees in this forested region are somewhat stunted and are not so fine as those of British Columbia, a region which in its physical features, climate, and natural vegetation greatly resembles Southern Chile. Some lumbering and fishing are carried on. Sheep are bred round Puerto Montt, in the north, and Punta Arenas (Magallanes), on the Strait of Magellan. There is an oil-field in Tierra del Fuego.

43. COFFEE IN BRAZIL AND A WHALING SHIP

(Above) A drying ground on a fazanda, Sao Paulo state, Brazil. The coffee beans have been brought from the plantation and men with big brooms are spreading them over the concrete 'flats' to dry. (Below) South Georgia: cutting up a whale on the deck of the 'Mother' ship of a whaling fleet. The whale blubber is fed to huge vats, where it is converted into whale oil (see p. 464).

44. PERU—AN IRRIGATED VALLEY AND LLAMAS

(Above) An irrigated valley in the Peruvian Andes (see p. 467) (Below) A pack-train of llamas carrying ore near Oroya. The llamas cover about 12 miles a day, and carry loads of from 75 to 100 lb.

(2) **The Central Vale of Chile**, lying between the Coast Range and the main chain of the Andes, is 600 miles long and some 30 miles wide. The north has a Mediterranean climate, though in the valley itself, where the influence of the sea is not strongly felt, the summers are warmer and the winters cooler than along the coast. Wheat, barley, oats, and maize are grown. Vines are cultivated (mainly for wine) as well as cool and warm temperate fruits such as apples, plums, apricots, peaches, and citrus fruits like oranges and lemons. Sheep are bred for mutton, wool, and hides; and wool is also obtained from alpacas and llamas, which are widely used for transport in mountainous districts. Beef and dairy cattle are reared for meat and other produce required for home consumption, but supplies of meat are insufficient to meet the demand and considerable quantities are imported from the Argentine. *Concepcion* is the chief town in the south of the Vale of Chile. Close by, an iron and steel plant lies within easy reach of a coal-field at *Coronel*, where the workings extend under the bed of the sea. On the slopes of the Andes copper is mined at *El Teniente*, south-east of *Santiago* (1,350,000), the capital. It is 150 miles from Santiago to *Valparaiso*

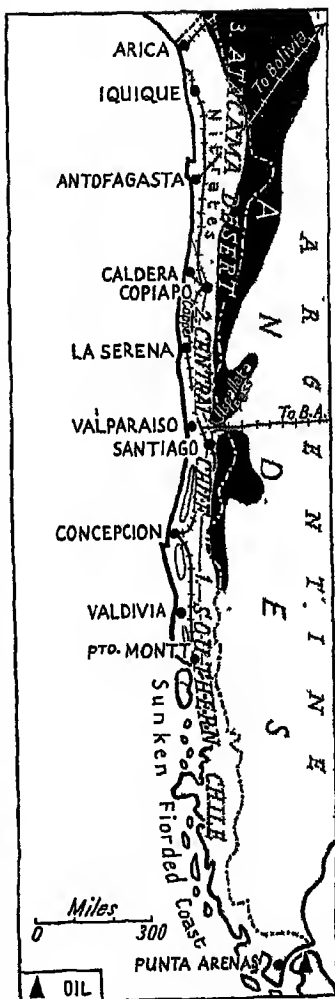

FIG. 274. Chile: Natural Regions.

(260,000), the chief port of Chile, and the western terminus of the 800-mile Transandine Railway. Valparaiso imports and refines sugar, manufactures textiles and furniture, and rolling stock for use on Chile's 6,100 miles of railway. At Concon, just north of Valparaiso, a refinery has recently been built to process oil from the Tierra del Fuego oil-field.

(3) **Northern Chile.** Despite its arid nature, characterized as it is by an entire absence of rain and a barren harbourless coast, Northern

EXPORTS OF CHILE		
Copper	Nitrates & Iodine	Rest

FIG. 275.

Chile is the chief source of the country's wealth, supplying nearly 80 per cent. of the total exports. Of this amount nitrates and iodine (a by-product obtained from nitrates) provide 18 per cent., and cop-

per 65 per cent. The *nitrate belt* extends through the Atacama Desert for 450 miles, lying at a distance of from 15 to 90 miles from the coast, and at elevations ranging from 3,500 to 10,000 feet. In this region, as there is no rain to wash the salts out of the soil, the nitrates have accumulated in the form of vast deposits, lying in layers a small distance below the surface. After the covering layers have been removed the nitrates are dug up and are taken to sheds, where they are crushed; and, after they have been dissolved in hot water to separate them from the sand and clay, the solution is evaporated and the salts crystallized out. They are then transported by rail to *Iquique*, *Antofagasta*, and *Caldera*, where the sacks are loaded on board steamers anchored alongside modern docks. Nitrates are exported for fertilizers and for making nitric acid. But in recent years the demand has fallen owing to the competition of synthetic and by-product nitrogen.

Chile ranks second to the United States in its output of *copper*, but first as an exporting country. Copper is mined near Copiapo, but even more comes from the north, where there are huge open mines and smelters at *Potrerillos* and *Chuquicamata*, a town linked by rail with *Antofagasta*, the main copper-exporting port. *Antofagasta* and *Arica*, farther north, both export tin from Bolivia. From *iron* mines in the *La Serena-Coquimbo* area, ores are shipped to the United States and to the smelter near Concepcion.

PERU AND BOLIVIA

Peru and Bolivia, taken as a whole, may be divided into three regions: (1) the Coast-lands between the Andes and the Pacific; (2) the Andes; and (3) the forested Montana Region sinking to the Lowlands of the Amazon Basin.

(1) **The Coast-lands.** South of the Gulf of Guayaquil lies a rainless region, where the winds blow off-shore or parallel to the land at

FIG. 276.

all seasons. The Peruvian coast lacks good natural harbours, and the marginal lands are arid and sandy except in the river valleys. But the waters of short, snow-fed streams descending from the Andes are used to irrigate many valleys, thus forming vertiable 'Little Egypts' in an otherwise barren region. Cotton and sugar-cane—the only two important agricultural exports of Peru—are widely grown in such valleys. The main sugar-producing area is in the north, where Trujillo is the chief port of export.

(2) **The Andes,** with their parallel chains, longitudinal valleys, and high intermont plateaux, rise to volcanic and other peaks, whose heights exceed 20,000 feet. On the plateaux, at elevations ranging from 9,000 to 11,000 feet, maize, wheat, barley, oats, and potatoes are grown. The agricultural methods of the Indians are primitive. After rough wooden ploughs drawn by yokes of oxen have lightly

furrowed the ground, the seed is scattered broadcast. The ripened grain is cut by hand and carried to the threshing floors, where it is either trodden out by oxen, or beaten with flails.

On the higher lands, up to 13,000 feet, cattle and sheep are grazed, as, too, are those dwarf camel-like creatures llamas and alpacas; and

FIG. 277. Peru and Bolivia : Relief, Communications, and Irrigated Areas.

their untamed relations the guanacos and vicuñas wander over the mountain side. The sure-footed llamas are the chief transport animal of the Andes, and their coats, like those of the alpacas, yield wool, for which Arequipa is the chief collecting centre and market.

(3) **The Montana** or forest region stretches along the eastern slopes of the Andes, whence steep tropical valleys, called *yungas*, lead to the *selvas* of the Amazon. The *montana* produces coffee, and coca, whose leaves are used for manufacturing cocaine. Wild rubber, nuts, and timber are obtained from the *selvas*.

The *mineral wealth* is considerable. Petroleum is a leading export

of Peru, where the main field is near Talara. Much copper is mined, especially near Cerro de Pasco, whence ore is sent by rail to Oroya, and there smelted over local coal and turned into bars for export from Callao. Bolivia, is rich in *tin*, silver, copper, and lead. It ranks third as a tin-producer, following Malaya and Indonesia. From Oroya and other centres tin concentrates are shipped through Antofagasta to the United Kingdom. Silver is mined at Potosi, but output has recently declined. The Camiri oil-field in the south-west produces enough oil for Bolivia's needs.

The steepness of the Andes, and the great height of even the lower

Petroleum	

FIG. 278.

passes, make road and railway construction difficult. There are few good roads and, apart from short railways serving the irrigated valleys, there are only five lines (two with terminal ports in Northern Chile) connecting the coast-lands with the interior.

Lima, the capital of Peru, is connected by rail with *Callao*, the chief port. Beyond Lima the line zigzags up the mountains, passing through the Gelera tunnel at a height of 15,693 feet before reaching Oroya, whence it continues to Cerro de Pasco. From *Mollendo* a railway runs through *Arequipa*, situated in an irrigated valley, to *Puno* on Lake Titicaca, the centre of an inland drainage area. Shortly before reaching Puno a branch line runs north to *Cusco*, the capital of the former Inca Empire.

As Bolivia has no seaboard the railways linking it with the Pacific run through Chilean or Peruvian territory. From Arica a line runs to *La Paz*, the chief city of Bolivia, standing south-east of Lake Titicaca, at a height of 12,000 feet. This line runs south to Oruro and thence, after sending a branch to *Potosi*, reaches Uyuni, where it divides: one branch running south-west to the Pacific coast at Antofagasta, the other going south-east to Buenos Aires, a three days' journey by rail from La Paz.

EXERCISES

1. Give a careful account of the Andes mountain system from the point of view of relief and drainage. Describe the natural vegetation on the eastern and western slopes of the mountains in their different sections and show how it is related to climatic conditions. Illustrate your answer by a sketch-map.

2. Draw a map of the west coast of South America and on it show the direction of the prevailing winds in (i) summer and (ii) winter. Distinguish, by appropriate shadings, between the areas receiving (i) rain at all seasons, (ii) little or no rain, and (iii) rain during winter only.

3. (a) On a sketch-map of South America mark and name the chief belts of natural vegetation. (b) Describe the natural vegetation of the *savannas* of the Amazon basin. Name four trees and four cultivated plants typical of this region. (c) Describe the position of one extensive tropical forest area outside South America. (d) How does the natural vegetation affect (i) settlement, and (ii) transport in tropical forest areas. (e) How do the amount and seasonal distribution of rainfall and high temperature affect the vegetation of the *campos* of Brazil? Name two trees and two crops grown on the *campos*.

4. (a) Describe four of the chief factors that have contributed towards making the state of São Paulo, Brazil, the chief coffee-producing area in the world. (b) Name in order of importance the three chief coffee-exporting ports of Brazil. (c) To what countries is the Brazilian crop chiefly exported? (d) Name three other coffee-producing countries.

5. (a) Draw a sketch-map of Argentina to show the chief natural regions into which it may be divided. (b) State briefly the relation of natural vegetation to climatic conditions in each of the natural vegetation regions. (c) State, giving your reasons, which of the regions into which you have divided Argentina makes the most important contribution to the life of the country.

6. (a) Name one drawback from which Bolivia suffers in the competition for world trade. (b) What other country in South America suffers from a similar drawback? Name the chief exports of Bolivia, and state through what seaports they are chiefly exported.

7. (a) Name the chief crops cultivated on the high plateaux of Peru and Bolivia. State briefly what you know of the agricultural methods practised. (b) Name the chief animals bred on the plateaux. What product or products obtained from them enter into world trade? (c) Name one animal largely used for transport purposes in the Andes, and state how it is adapted to the geographical conditions.

8. Draw a map of South America and on it shade the most densely peopled areas. Account, so far as you can, for the density of population in these areas.

9. (a) On a sketch-map of the west coast of South America (i) shade the high land, (ii) mark and name the chief ports from which railways lead to the interior, and mark the lines in question. (b) In the case of each port give some account of its trade. (c) In what way are the majority of these ports handicapped for handling goods? (d) With what country do they mostly trade, and what factors have played a great part in developing that trade?

10. (a) Describe a railway journey from Valparaíso to Buenos Aires, paying attention to (i) configuration, (ii) regions and occupations of the people of the area traversed by the railway. (b) Name one other railway which crosses South America from the Pacific to the Atlantic, and mention two terminal ports and three towns *en route*.

11. Under the headings (i) position, (ii) relief and climate, (iii) products, (iv) communications and towns, write an account of Colombia and Venezuela treated as one area.

12. Divide the Guianas into Natural Regions. For each region (i) describe the characteristic features, and (ii) mention the chief crops, and in the case of one of them show why the area is well suited to its production.

13. Illustrating your answers by sketch-maps, describe the position and trade of Rio de Janeiro, Montevideo, and Belém (Para).

14. (a) Draw a sketch-map of Chile, showing the chief Natural Regions into which it may be divided. In the case of each region name two products and two towns. (b) State, giving your reasons, which region is best suited for settlement. (c) Which of the regions is the greatest source of wealth to Chile? State the chief products of this region. To what country are they mainly sent, and why?

15. (a) Name *three* important industries carried on at Buenos Aires. Account for the location of any *two* of them in this city. (b) Name *one* other town in Argentina, *one* in Brazil, and *one* in Uruguay, each of which has for similar reasons *one* of the industries carried on at Buenos Aires. In each case name the industry.

TEST PAPER: SOUTH AMERICA

PART I

1. Compare North and South America under the headings: (i) physical features; (ii) climate; (iii) natural vegetation.

2. Draw a sketch-map of the Panama Canal. How has its construction affected the trade of the west coast ports of South America? From what disadvantages do most of these ports suffer?

3. Draw a fully labelled sketch-map to show why the Atacama Desert is rainless. Discuss the importance of this region to Chile.

4. (a) Draw a sketch-map showing the chief regions into which Brazil may be divided. (b) Select one of these regions and describe it under the headings: (i) the relations of the physical features and climate to the natural vegetation; (ii) occupations of the inhabitants as affected by environmental conditions; and (iii) overseas trade.

5. Name the chief Commonwealth territories in Central and South America (including the West Indies). Write a geographical account of one of them and describe its trade with Britain.

PART 2

6. Compare the Argentine pampas with the Prairie Provinces of Canada with regard to (i) position in relation to world markets; (ii) climate; (iii) farming activities.

7. Why is the term *Latin America* often applied to the Americas from Mexico southward? What Latin races colonized this area? In what respects is their influence seen to-day?

8. Explain (a) why farms in Patagonia are usually very large; (b) why the bulk of South American ores are sent to other countries to be smelted; (c) why the hydro-electric resources of the Argentine Andes are relatively little utilized; and (d) why the Andean region is subject to earthquakes.

9. Name *two* important raw materials, and *three* food products that South America contributes to the needs of Great Britain. In each case mention *one* area of production and the chief port of export for that area. Selecting *one* of the food products, describe the conditions that favour its production in the area you have named.

10. What do you mean by (a) *river capture*, and (b) *inland drainage*? Illustrate your answers from South America.

PART VII

AUSTRALIA, NEW ZEALAND, AND THE
PACIFIC ISLANDS

CHAPTER XXXII

AUSTRALIA

GENERAL SURVEY OF AUSTRALIA_

THE Commonwealth of Australia includes, in addition to the mainland of Australia, the island of Tasmania in the south. Papua (south-eastern New Guinea) and the Territory of New Guinea (north-eastern New Guinea) are separately administered by the Commonwealth, which governs the latter Territory under the Trusteeship system of the United Nations. Australia is bounded on the north-west and west by the Indian Ocean, on the south by the Southern Ocean, and on the east by the Pacific. Their remote position in the Southern Hemisphere, coupled with their great distance from Europe, long retarded the development of Australia and New Zealand; while in more recent times their relative isolation has done much to stimulate in their inhabitants an independent outlook.

The mainland of Australia extends from 10° S. almost to 40° S., a distance of approximately 2,100 miles; while the Tropic of Capricorn crosses the continent in its widest part. Nearly 3,000,000 square miles in area, Australia comprises almost one-fifth of the British Commonwealth, but despite its size a considerable proportion is unsuited to settlement owing to its arid nature. A compact mass, the continent shows marked physical and climatic resemblances to South Africa, and, like the latter, has few indentations. The only really large opening is the Gulf of Carpentaria, in the north, for the Great Australian Bight, in proportion to its width, makes a relatively slight entry in the south.

In remote ages Australia was joined to Asia, but its separation was effected at a very early period. Before this took place the continental shelf which stretches from the north coast of Australia towards South-east Asia, and is now covered by shallow seas, was probably dry land. On the south the shelf extends beyond Tasmania; on the north-east its edge is marked by the Great Barrier Reef.

STRUCTURE AND RELIEF

Australia may be divided into three main physical regions.

(1) **The Western Plateau**, occupying more than half of Australia, is an ancient, much denuded crust-block. It varies in height from

FIG. 279. Australia: Physical Features.

600 to 1,500 feet, though here and there ranges, like the Macdonnell and Musgrave Ranges, bulge above the general level.

(2) **The Eastern Highlands**, or Great Dividing Range, form the eastern edge of the Western Plateau, extending along the Pacific coast from Cape York almost to the mouth of the Murray. The Highlands slope gradually to the interior, but on their seaward side rise from the plains by steep escarpments, which form barriers to climatic influences and communications.

(3) **The Central Lowlands**, stretching from the Gulf of Carpentaria to the south coast, which they reach round the mouth of the Murray, may be divided into (a) the Murray-Darling Lowlands,

(b) the Lake Eyre Basin, part of the inland drainage area of Australia, and (c) the Carpentaria Lowlands drained to the Gulf of Carpentaria. It should be noted that Lake Eyre lies in a *rift valley*, which extends south through Lake Torrens to Spencer Gulf.

Rivers. A number of relatively short, swift rivers, like the Hawkesbury, Fitzroy, and Burdekin rivers, flow from the Eastern

FIG. 280. Australia: Artesian Basins (after Griffith Taylor).

Highlands into the Pacific. The Flinders and the Roper drain into the Gulf of Carpentaria. On the west coast the chief rivers are the Victoria, navigable for 100 miles, Fitzroy, Murchison, and Swan Rivers, which fall into the Indian Ocean.

The Murray, the chief river, enters the sea through Lake Alexandrina, a shallow lagoon almost separated from the ocean by a sandspit which prevents access by ocean-going vessels. The main value of the Murray and its tributaries is for irrigation.

It is improbable that the greater part of the arid interior of Australia will ever be reclaimed, though in certain areas a transformation has been wrought by sinking *artesian wells*. Such wells are sunk to obtain water imprisoned, often at great depths, between impervious rock strata. A hole is bored by means of a drill, and when the supply is reached pressure is released and the water rushes to the surface.

A right-angled iron pipe is inserted at the head of the bore, and the water flows into a pool, from which shallow channels lead it over the land. The *Great Artesian Basin*, which covers an area of over half a million square miles, stretches from the Gulf of Carpentaria, across the Central Lowlands, through Queensland into New South Wales. The sinking of artesian wells has enabled this vast region to be developed for stock rearing, and has made it possible for the great stock routes to be kept open, even during exceptionally dry periods. Other artesian basins, as yet little developed, are the Murray Basin; the Eucla Basin, stretching inland from Eucla, on the Great Australian Bight; the Perth Basin; the North-West Basin, round Shark's Bay on the west coast; and the Desert Basin, extending for 400 miles east of Broome.

CLIMATE

The whole of Australia lies north of 40° S., which corresponds to the latitude of Southern Italy, while somewhat more than one-third is situated north of the Tropic of Capricorn. Thus nowhere, except in the highlands, is Australia really cold, and in the north temperatures are uniformly high. Most of Australia lies in the belt of the south-east trades, which, though they cause adequate rainfall on the windward slopes of the eastern Highlands, blow over the greater part of the continent as dry winds. The comparatively light rainfall is associated with absence of clouds and abundant sunshine. The average number of hours of sunshine per year at Perth is 2,810, compared with 1,480 in Eastern England.

Temperature. In *January* (summer) almost the whole of Australia has a temperature of over 72° F. North of the tropic temperatures exceed 80° F., and in the interior they are well over 90° F.

In *July* (winter) most of the region north of the tropic has a temperature of over 64° F. and is thus warmer than the South of England in summer. Nowhere south of the tropic (except in the highlands) is the mean July temperature less than 48° F., though on winter nights frosts occur, for in the dry clear air heat radiates rapidly.

Rainfall. As we have seen, the south-east trades precipitate most of their moisture on the windward side of the Eastern Highlands, becoming drier and drier as they blow over the interior. Rainfall decreases rapidly westward, and rain only occurs at rare intervals

during thunder-storms. The movement of the wind and rainfall belts, which move north and south with the apparent movements of the sun, affects the rainfall.

FIG. 281. Australia: January (Summer) Temperature.

FIG. 282. Australia: July (Winter) Temperature.

(1) *Summer conditions.* In the Australian summer the wind belts move south with the apparent movements of the sun.

(a) The south-east trades now blow on-shore along nearly the whole of the east coast, causing rain, which is especially heavy in the north.

(b) In the extreme south the winds blow off-shore and little rain falls.

(c) The interior of the continent is extremely hot, forming a region of low pressure with in-flowing winds. In the north of Australia monsoon winds, blowing from South-east Asia across the Indian Ocean, cause heavy rains to fall.

FIG. 283. Australia: Summer Rainfall.

FIG. 284. Australia: Winter Rainfall.

Tasmania, lying in the brave west-wind belt at all seasons, receives rain throughout the year, especially on the western slopes of the mountains, which are much wetter than the leeward slopes.

(2) *Winter Conditions.* In the Australian winter, when the sun is overhead at noon somewhere between the equator and the Tropic of Cancer, the wind and rainfall belts move north.

(a) The extreme south of Australia now lies in the west-wind belt

of variable rains. Like the south-west of Africa and Central Chile, it has a typical Mediterranean climate.

(b) The east coast-lands, from the south of Queensland northwards, receive winter rains from the on-shore south-east trade winds.

(c) In the north of Australia the south-east trade winds, in winter, blow off-shore towards South-east Asia, and thus at this season the northern part of the continent is dry.

FIG. 285. Australia: Mean Annual Rainfall.

NATURAL VEGETATION AND WILD ANIMALS

Owing to the long isolation of Australia, many primitive forms of animal life have survived; while numbers of its plants are quite different from those in other parts of the world. The animals include specimens of the early mammals, including the marsupials like the kangaroo and the opossum, both of which carry their young in a pouch; and the platypus, an amphibious animal which has a bill like a duck and webbed feet and, though a mammal, lays eggs like reptiles. The echidna or Australian ant-eater resembles a large hedgehog; and the koala is a small tree-climbing bear. Among the birds in the northern forests are the crested cockatoo and the lyre bird, which has remarkable powers of mimicry. Many of the plants go back to the Mesozoic period. The lily, honeysuckle, tulip, and other plants are found in Australia as trees. The most typical Australian tree is the eucalyptus, of which there are several hundred varieties. These trees shed their bark instead of their leaves, which hang edgewise to the sun to reduce evaporation.

A comparison of the rainfall (Fig. 285) and vegetation maps (Fig. 286) shows that there is a close connexion between the two. Roughly, the different vegetation belts occur in concentric circles around the arid interior, increasing in luxuriance with increasing rainfall.

Belts of *tropical forest* occur along the north and north-east coasts,

FIG. 286. Australia: Natural Vegetation.

where the monsoon rains last for five months and the annual rainfall is about 65 inches. But these forests are not continuous, being interspersed with stretches of more open savannas.

Savanna forests cover the greater part of the monsoon rain area, while on the east they extend southwards into the north of New South Wales. They consist mainly of grass-lands with eucalypts. As the rainfall decreases towards the interior, the savanna forests merge into true savannas, which gradually merge into the belt of salt bush on the desert margin.

In the *desert* itself, with its long, wind-swept ridges of reddish sand, the vegetation consists of mulga and porcupine grass, though after

very rare rain-storms it is transformed and, for a brief space, is clad with a vivid carpet of green vegetation.

The *warm temperate rain forests* of the south-west and south-east consist of rich grass-land with many eucalyptus trees. The former region is the richest timber area in Australia.

FIG. 287. Australia: Distribution of Sheep.

Much of the Murray-Darling Basin consists of *grass-lands*. As the rainfall decreases towards the west, these natural pastures pass into the *Mallee Scrub* (eucalypts) that margins the Great Australian Bight and extends, north of the south-west forest, to the west coast.

Tasmania has much *forest* land. In the wetter west the chief trees are beech and pine; but in the drier east eucalypts predominate.

CROPS AND ANIMALS

Australia is the chief *sheep-producing* country in the world. The climate is admirably suited to sheep, which thrive in dry areas where the rainfall is between 10 and 20 inches per annum, and the summer

temperatures do not exceed 75° F. For these reasons few sheep are found along the east coast-lands, where the damp climate is better suited to dairy cattle; in the north, where temperatures are too high; or in the interior, where the rainfall is under 10 inches per annum. Apart from these regions, sheep are widely spread. The main sheep

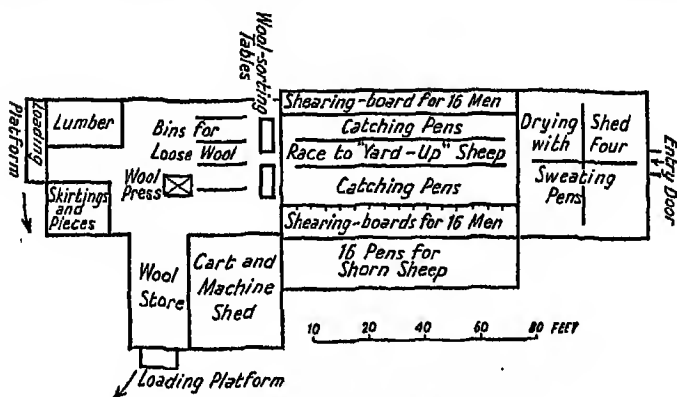

FIG. 288. Plan of an Australian Wool-shed.

FIG. 289. Comparative Output of Sheep.

1. Australia; 2. U.S.S.R.; 3. U.S.A.; 4. South Africa; 5. Argentine;
6. New Zealand; 7. British Isles; 8. India and Pakistan.

belt lies on the leeward side of the Eastern Highlands, stretching from the Murray Basin northward to Central Queensland. Within this area New South Wales has nearly half of the 150,000,000 sheep in Australia, and this state also carries the greatest number per square mile. In the drier regions there are fewer sheep to the square mile; the farms are larger, some having an area of over 50,000 acres. In districts where the rainfall is relatively great sheep are grazed both for wool and mutton; in those with small rainfall they are bred mainly for wool.

The sheep are sheared in spring, and the bales of wool are

conveyed by large motor-wagons (with or without trailers) to the nearest railway, whence they are dispatched to the port of export. Sydney and Melbourne are the leading wool markets of the world, though London is still an important centre. Great Britain and Japan are the chief importers of Australian wool. In addition to

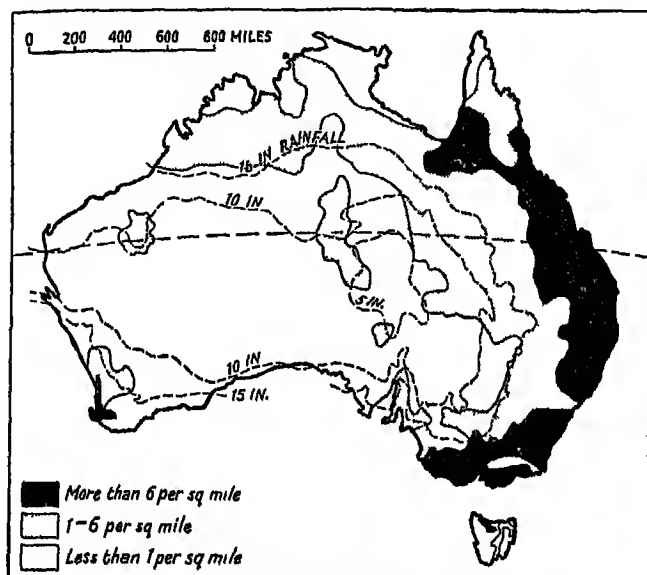

FIG. 290. Australia: Distribution of Cattle.

mutton, by-products of the sheep industry include skins tanned for leather, horns, hoofs, and tallow.

There are 17,300,000 (1961) *cattle* in Australia, of which about 75 per cent. are bred for beef and the rest for dairy purposes. Cattle require more moisture than sheep, but are better able to withstand high temperatures. The chief producing areas are in the wetter north and along the coastal plains of the east. Nearly half the beef cattle are bred in Queensland, where a great proportion are pastured in the great Artesian Basin.

The principal dairying regions are in the wetter south-east, especially in the lowlands near the coast, where the annual rainfall

exceeds 30 inches. Eighty per cent. of the milk is made into butter, which ranks fourth in the export list. Somewhat less than half is used in Australia, and of the remainder the greater part is exported to Great Britain, while some is marketed in Indonesia.

The introduction of refrigeration revolutionized the sheep and

FIG. 291. Australia: Distribution of Wheat.

cattle industries in areas of large-scale production. It is only since the advent of refrigeration that Australia has been able to export chilled and frozen beef and mutton and dairy products—butter, cheese, and eggs. Much beef is exported to the United States; mutton and lamb go mainly to the United Kingdom.

Since the beginning of the present century the amount of land devoted to agriculture in Australia has more than doubled. *Wheat* alone now occupies 70 per cent. of the total area under cultivation. With the exception of a comparatively small acreage in Queensland, the crop is confined entirely to temperate Australia. The greater part is produced in areas having an annual rainfall between 20 and 30 inches; and none is grown where the rainfall is less than 10

inches. An important grain belt extends from the district north of Adelaide, in South Australia, eastward through Victoria and New South Wales. The south-west of Western Australia is another wheat-growing region.

The mild, sunny climate favours *fruit farming*. Much fruit is grown, especially on irrigated lands in the Murray basin, where apricots, peaches, and pears are dried or canned for export. Vines, too, are grown both for currants and raisins, and, in districts such as the hills round Adelaide, for wine. Oranges and other citrus fruits are cultivated on irrigated coast-lands in northern New South Wales; pineapples on the tropical lowlands of Queensland; Tasmania, with its cooler, damper climate, produces half the apple crop of the Commonwealth. There are many sugar plantations at widely spaced intervals along the Queensland coast. The cane is grown and the sugar produced entirely by white labour, and the industry is controlled by the Government through high tariffs, wages boards, and price-fixing awards. There is a surplus of sugar for export, since production exceeds the demands of the home market by half a million tons a year. Cotton is grown only in Queensland, but the amount is quite insufficient for Australia's needs.

MINERALS

Australia is rich in minerals, especially gold, coal, silver, lead, zinc, copper, and tin. The Australian mines, unlike those of South Africa, are worked entirely by white labour. At the present time Western Australia produces nearly 75 per cent. of the country's total output of *gold*. In this State the mineral is found mainly in the south-west, the chief mines lying in the desert region, to which water has to be conveyed through pipes from a reservoir near Perth, 300 miles distant from the nearest mine. On the extensive Coolgardie field are Kalgoorlie (Australia's chief gold-mining centre) and Boulder, with Leonora to the north, and Bullfinch to the west. To the south is Norseman. All these places are on the main or on branch lines of the Trans-Continental Railway from Perth to Port Augusta. Another line connects Cue and Wiluna on the Murchison field with Geraldton. Farther north are Marble Bar on the Pilbara gold-field and Hall's Creek on the Kimberley Plateau. Gold is also mined at Tennant Creek, Northern Territory, and Mount Morgan in Queensland.

Broken Hill (N.S.W.) is noted for *silver*, *lead*, and *zinc*. After the ores have been smelted the concentrates are sent by rail to Port Pirie, where the silver and lead are refined, and zinc is shipped to Risdon (near Hobart), where falls supply power

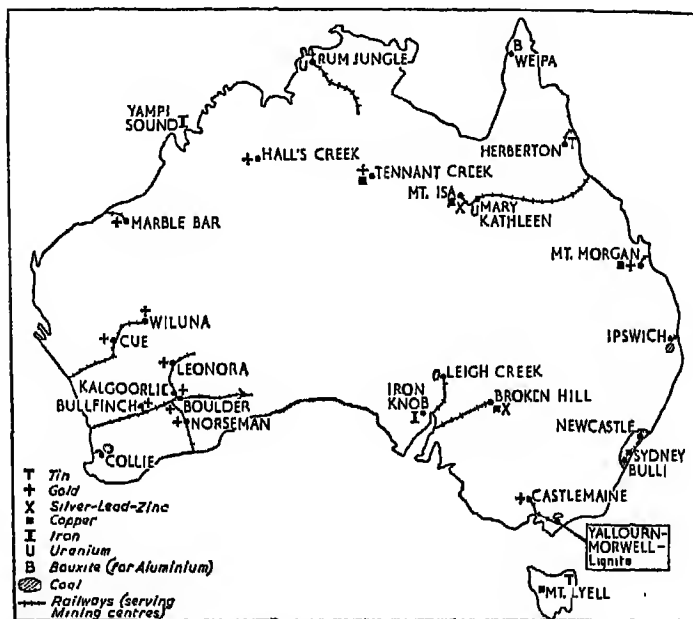

FIG. 292. Australia: Distribution of Minerals.

for an electrolytic-zinc industry. Mount Isa (Queensland) is also important for silver-lead-zinc. Mount Isa accounts for half Australia's output of *copper*, also obtained from Mount Lyell (Tasmania), Mount Morgan, and Broken Hill. Some *tin* is mined in north-east Tasmania and at Herberton (Queensland).

Uranium is mined at Rum Jungle (N.T.), and Mary Kathleen (near Mt. Isa), but the Radium Hill mine (S.A.) has closed down. From Iron Knob (Eyre Peninsula), and Yampi Sound (W.A.) *iron ore* is shipped to blast furnaces at Newcastle and Port Kembla. *Bauxite* is worked at Weipa in the north-west of Cape York Peninsula.

The *New South Wales Coal Basin*, the most important in the Southern Hemisphere, extends from Sydney, north to Newcastle and south to Bulli. The coal lies close to the coast, which thus facilitates export. About half the coal in Queensland is obtained

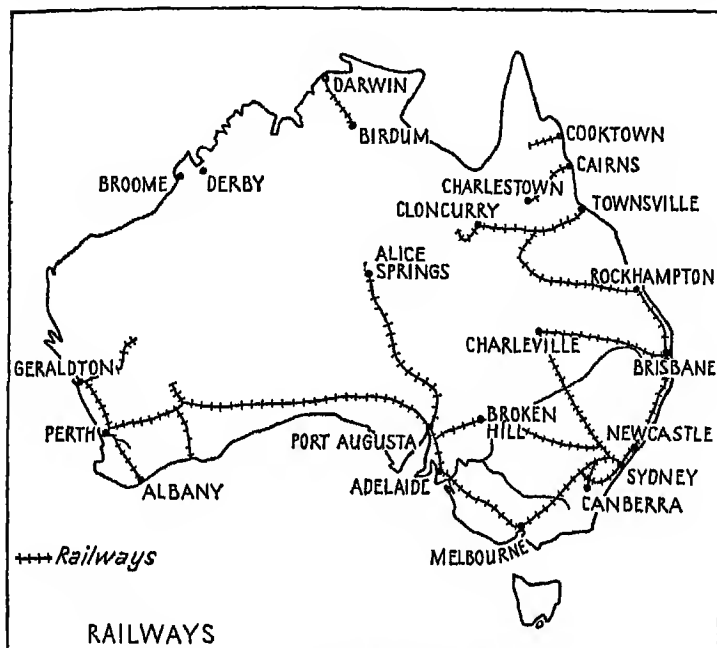

FIG. 293. Australia: Railways.

from the *Ipswich* field, near Brisbane. In Victoria, enormous deposits of brown coal are worked by open cast methods at *Yallourn*, 90 miles east of Melbourne. In South Australia coal is mined at Leigh Creek, and in Western Australia at Collie, not far from the port of Bunbury.

COMMUNICATIONS

The distribution of minerals, especially gold, had a great effect on the development of railways in Australia. Apart from their immediate purpose, the lines built from the ports to inland mining centres played no small part in the opening up of the country.

Unfortunately, when railway construction was first undertaken no standard gauge was decided on for the whole of Australia, and as a result there are at the present time four different gauges.¹ Thus a railway journey from Perth to Brisbane, 3,500 miles, takes 170 hours (or twice as long as to cover the same distance from New York to San Francisco) on account of five changes of gauge and six changes of train.

Airways. In a country so isolated, and with such great internal distances as Australia, air transport plays an important part in both overseas and inland communications. Canberra and all the State capitals, including Hobart, are linked by air. A journey between Melbourne and Sydney takes only 2 hours by air compared with 15 hours by rail. Regular air services connect Sydney with New Guinea, New Zealand, North America, Asia, Africa, and continental Europe and England, via Darwin, Singapore, Calcutta, Cairo, and Rome. Mascot (Sydney), the focus of thirty air routes, handles more traffic than any other Australian airport.

Many smaller towns are linked by air services. 'Flying Doctor' Services, operating from certain bases, enable people in remote areas to call up their nearest base on a pedal wireless and consult a 'Flying Doctor', who prescribes treatment, or, if needs be, flies out and brings back the patient to hospital.

POLITICAL DIVISIONS AND DISTRIBUTION OF POPULATION

The Commonwealth of Australia consists of the states of *New South Wales, Victoria, Queensland, South Australia, Western Australia, and Tasmania*; together with the *Northern Territory* and the *Australian Capital Territory* (940 square miles). Out of a total population of 10,500,000 (1960), about 50 per cent. live in the five State capitals of Sydney, Melbourne, Brisbane, Adelaide, and Perth. All these great cities are ports, and as the wealth of the country lies largely in its export trade, it is in these busy centres that the majority of the people find employment.

Climatic conditions, especially rainfall, provide the key to the general distribution of the population. At least four-fifths of the

¹ *Gauges*: New South Wales and Federal Lines 4 ft. 8½ in.; Victoria and South Australia 5 ft. 3 in.; Queensland 3 ft. 6 in. and 2 ft.; Western Australia and Tasmania 3 ft. 6 in.

45. SHEEP IN AUSTRALIA

(Above) Mustering sheep on a New South Wales 'station', ready for dipping and shearing.
(Below) In a shearing shed. The shearers use electric clippers to clip off the fleece: a skilled man can shear 200 sheep in a day.

46 NATURE AND MAN IN AUSTRALIA

(Above) The Great Barrier Reef of Australia at low tide. Stretching for 1,200 miles along the Queensland coast, it is the work of coral polyps. (Below) The great single-arch bridge spanning Sydney Harbour connects the main city with North Sydney. It was built by British engineers. Photographs by the Development & Migration Commission and Jasper Stembidge.

inhabitants live in well-watered regions along the temperate coastal belt of the east and south-east, and in the south-west corner of Western Australia. The arid interior, with an annual rainfall of less than 10 inches, and comprising over one-third of the country, is

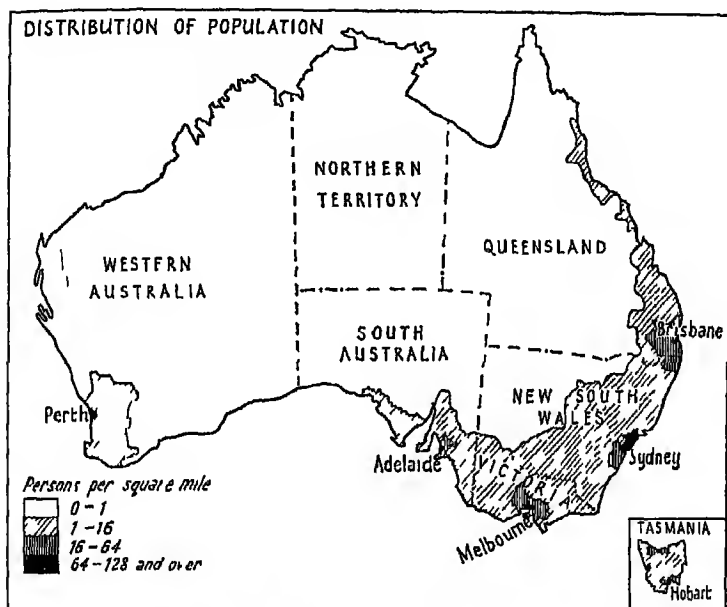

FIG. 294. Australia: Distribution of Population.

sparsely populated, while the tropical north is probably unsuited to close white settlement, though the people living in the north are usually strong and healthy. In the Northern Territory (523,620 square miles), which includes a considerable proportion of both arid and tropical belts, the total population is only 35,000, including 16,000 aborigines. The Territory might support more people if ranching were extended, and there were better transport facilities, and more watering points along stock routes.

The white workers exclusively employed on Queensland sugar plantations, performing such tasks as cutting canes under a blazing

tropical sun, or toiling in the steamy atmosphere of the filter presses, command high wages for their arduous work. The average Queensland cane cutter earns as much in a day as a native cutter in Java gets in a month. Thus in Queensland production costs are high in the sugar industry, which is aided by subsidies and protective tariffs. But this industry has proved that it is possible to provide agricultural employment for white people working under tropical conditions, and thus supports Australia's contention that it is possible to colonize her tropical areas with whites and so retain the whole continent as 'A White Australia'.

REGIONS OF AUSTRALIA

South-Eastern Australia. Politically South-eastern Australia comprises New South Wales, Victoria and the south-east of South Australia. This portion of the continent falls into five Natural Regions: (1) the Eastern Highlands; (2) the East Coast Lowlands; (3) the Great Victoria Valley; (4) the Murray-Darling Basin; and (5) the South-east of South Australia.

(1) **The Eastern Highlands** rise steeply from the narrow coastal plain. In the north they form the New England and Liverpool Ranges, in the centre the Blue Mountains, and farther south the Australian Alps, beyond which they trend west and, running parallel to the coast, form the Victorian Highlands. These Highlands are a barrier to moisture-laden on-shore winds, and also a handicap to communications between the coastal belts and the interior plains of the Murray-Darling Basin.

(2) **The East Coast Lowlands** are the most densely peopled part of New South Wales. The rainfall varies from 30 to 50 inches, being greater in the north, where it is heaviest in the summer months. This damp climate favours dairying, but is unsuited to wheat; and though sheep are bred on the uplands, few are found on the lowlands. Maize and sugar-cane, both of which require a high summer temperature and abundant moisture, are grown in the warmer, wetter north. Temperate fruits are cultivated in the cooler south. *Sydney* (2,180,000), the capital of New South Wales, stands in the centre of the Great Coal Basin, on the magnificent silt-free harbour of Port Jackson. Railways run north and south along the coast, and north-west and south-west across the highlands to the Murray Basin, for which Sydney is one of the chief outlets. A large proportion of the

Australian wool is exported from Sydney, which is the principal wool market in the world. Other exports include butter, wheat, flour, fruit, and coal. *Newcastle*, a leading coal port, and *Port Kembla*, are the chief iron and steel centres in Australia.

The *Australian Capital Territory*, around *Canberra*, the Federal Capital, was carved out of New South Wales.

(3) The **Great Victoria Valley** lies between the Victorian

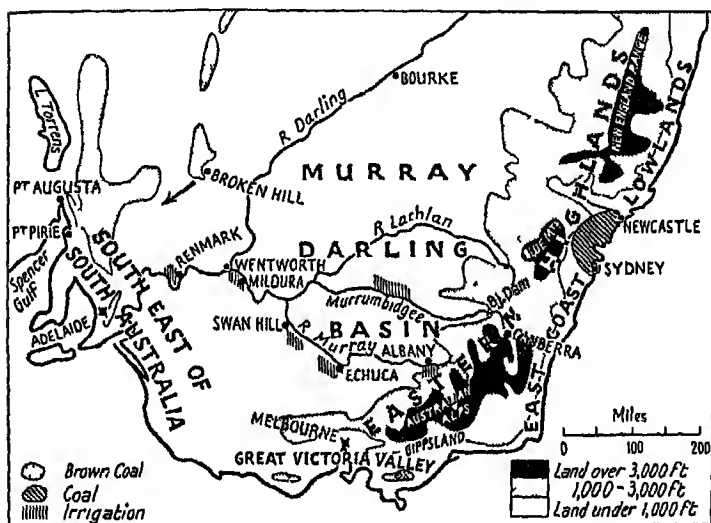

FIG. 295. South-eastern Australia.

Highlands and the Otway Range and Gippsland Hills, running west and east respectively from Port Phillip Bay. Dairying and mixed wheat and sheep farming are important. Brown coal is mined at Yallourn in Gippsland. Steamers of fair size can ascend the Yarra to Melbourne (1,900,000), the capital of Victoria, but larger vessels tie up at the piers or wharves of *Port Melbourne*, or dock at *Geelong*, a woollen-manufacturing centre, on the west side of Port Phillip Bay. Melbourne is the outlet for the Victoria Valley and the southern part of the Murray Basin. It ranks second to Sydney in size and as a wool market, and (except for coal) its exports are similar.

(4) The **Murray-Darling Basin** occupies about one-fifth of

Australia. The navigable waters of the Murray-Darling system, which total over 4,000 miles, were formerly used by commercial vessels as far as *Albury*, on the Murray, and from *Wentworth* to some hundreds of miles above *Bourke*, a sheep rearing centre on the Darling. Nowadays, rail and road transport are used, though tourist steamers ply between Mildura and Morgan, on the lower Murray.

The alluvial plains of the Murray Basin only need irrigating to make them yield rich crops. To hold back water for irrigation dams have been built across the rivers to form reservoirs, such as the Hume Reservoir, on the Murray, near Albury, and that formed by the Burrinjuck Dam, on the upper Murrumbidgee. Much fruit is grown on irrigated lands round Renmark and Mildura, and in the *Riverina*, the district between the lower Lachlan and the Murray. This district includes the *Murrumbidgee Irrigation Area*, noted for citrus fruits and vines, and dairy and sheep farming.

(5) **The South-East of South Australia** is the only really productive region in a state more than four times the size of Great Britain, but whose total population does not exceed 886,000. Somewhat more than half the people live in *Adelaide*, the capital, a few miles from Port Adelaide, on the Gulf of St. Vincent, which exports much of the produce of the Lower Murray. *Port Pirie*, on the east side of Spencer Gulf, the outlet for the famous Broken Hill mines, refines lead and silver, and ships zinc concentrates to Risdon, Tasmania. *Whyalla*, on the west side of Spencer Gulf, smelts iron ore from the Iron Knob area, 40 miles inland. It also ships iron ore to Port Kembla and Newcastle, return cargoes being coal and coke. *Port Augusta*, at the head of Spencer Gulf, exports wool and wheat from its extensive but dry hinterland.

Queensland. Though Queensland is the second largest state in the Commonwealth, its population is less than a million. Along the east coast the *Great Barrier Reef* extends from Torres Strait for 1,200 miles to about latitude 26° S. This belt of coral, from 10 to 90 miles wide, really consists of a number of reefs, many of which are separated by waters deep enough to admit the passage of large vessels.

Queensland may be divided into three Natural Regions: (1) the Coastal Lowlands; (2) the Eastern Highlands, known as the Great Dividing Range in the north, and the Darling Downs in the south; and (3) the Interior Plains, lying mainly in the Great Artesian Basin.

(1) **The Coastal Lowlands**, hot and wet throughout the year, especially in the north, are well suited to tropical agriculture, carried on exclusively by white labour. Bananas, pineapples, cotton, and

FIG. 296. Queensland.

sugar-cane are grown on the lowlands and maize at higher elevations. The cane plantations all lie within 30 miles of the coast between latitudes 16° and 30° S. The chief centres, separated by great distances, are *Mackay*, *Bundaberg*, and *Maryborough*. Cattle, too, are bred on the lowlands and slopes of the highlands: the bulk are reared for beef, but some dairying is carried on in the cooler south-

east. Coal is mined in the basin of the Brisbane river, round *Ipswich*, and near Rockhampton and Cairns.

Most of the people live in the coastal belt, where the chief towns, ports of moderate size, are situated. From these centres the earlier railways ran inland to the pastoral, mining, and agricultural areas, but now lines also run along the coast from Brisbane as far north as Cairns. *Brisbane* (555,000), the capital of Queensland, and only large town, situated some 12 miles up the Brisbane river, is the outlet for Southern Queensland and the adjacent districts of New South Wales. Meat-canning and stock-exporting ports are *Rockhampton*, on the Fitzroy river, and *Townsville*, farther north, whence a railway runs inland, through a rich cattle belt, to the mining centres of *Charters Towers*, *Cloncurry* and *Mount Isa*.

(2) **The Eastern Highlands** are broad, but comparatively low, with average elevations of from 2,000 to 3,000 feet. Cattle are bred on the wooded pastures, with sheep in the south. The chief mining centres lie in these uplands, including Mount Morgan, noted for gold and copper; Mount Isa for silver-lead and copper; Cloncurry for copper, and Herberton for tin, which is obtained by dredging.

(3) **The Interior Plains**, thanks to artesian wells, now form the main pastoral belt of Queensland. Almost half the cattle and nearly one-fifth of the Australian sheep are found in Queensland, and of these the majority are reared in this region.

Western Australia. Western Australia is the largest state in the Commonwealth, comprising nearly one-third of its total area. It is, however, the most thinly peopled, for it contains a considerable proportion of arid and desert land, while the fertile north-western region is as yet little developed. Climate is the key-note of Western Australia, which may be divided into three Natural Regions: (1) the Tropical North-west; (2) the Arid Region; and (3) the 'Mediterranean' South-west.

(1) **The Tropical North-west**, with summer rains, consists of open monsoon forests and savannas in the north and arid lands in the south. Cattle ranching is the main occupation. Cattle are shipped from Derby to Fremantle. Broome is a centre for pearl fisheries. Iron ore is mined at Cockatoo Island, Yampi Sound.

(2) **The Arid Region** extends from the interior southward to the Great Australian Bight, and westward to the coast between Roe-

bourne and Geraldton. In spite of the low annual rainfall, which is under 10 inches, sheep are bred along the coast and on some of the plateaux in the interior where, owing to increased elevation, the rainfall is slightly greater. The mining centres on the Murchison gold-field (see p. 485) are connected by rail with Geraldton. Farther

FIG. 297. Western Australia.

south, *Boulder*, *Kalgoorlie*, and other gold centres lie on the main transcontinental railway or on branch lines.

(3) **The South-West Region**, with its Mediterranean climate, is the most productive and populous part of the state. The distribution of natural vegetation, crops, and animals depends almost entirely on rainfall. The extreme south-west, with an annual rainfall exceeding 30 inches, is well forested, its exports of timber—especially jarrah and karri—exceeding those of any other Australian state. In the cleared areas, especially to the south-west of Bunbury, are apple and orange orchards and vineyards. To the north-east of the timber belt, where the rainfall ranges from 30 to 20 inches, is an agricultural

and pastoral area with wheat, cattle, and sheep. In the succeeding and drier belt sheep are grazed on pastures which grow more and more scanty towards the arid interior, whose only wealth lies in its gold mines.

This region lies remote from the more populous states of the east, but the transcontinental railway and air transport have both helped to lessen the effects of this isolation.

Out of a total population of 720,000 over half live in *Perth*, the capital, 10 miles up the shallow Swan River. Its port, *Fremantle*, exports wool, wheat, flour, fruit, and gold. To the south, *Kwinana*, has an oil refinery, steel works, and cement plant; while *Bunbury* exports coal from the Collie field and timber from its hinterland. *Albany*, on King George Sound, serves both the forest area and the wheat belt.

The Northern Territory. In the whole of the Northern Territory, whose area is slightly more than half a million square miles, there are—excluding 16,000 aborigines—only about 19,000 people. The monsoon forests of the north are gradually replaced by savannas, which grow poorer and poorer as they merge into the arid interior. Cattle rearing is the chief occupation: the principal ranching areas lie around the Roper and Victoria rivers, on the Barkley Tableland near the Queensland frontier, and round the Macdonnell Range in the interior, where the main centre is Alice Springs (the present northern railhead of the projected north-to-south transcontinental railway), whence stock are sent by rail to Port Augusta. Some pearl fishing is carried on in the waters bordering the low northern coast. From Darwin, the only port in the Northern Territory, and a staging-point on the Sydney-Singapore air route, a railway runs to Birdum, the railhead. This line serves uranium mines at Rum Jungle and Edith River, the former 60, the latter 180 miles from Darwin. Gold is mined at Tennant Creek.

Tasmania. The mountainous island of Tasmania, with an area of 26,000 square miles, is separated from the Australian mainland by Bass Strait, 150 miles wide. The rugged rain-drenched western highlands are densely forested, mainly with beech and pine. In the less rugged and drier east eucalypts abound, and pastures clothe the lower slopes of valleys and hills. The many rivers, fed by abundant rains and perennial snows, provide ample power for the generation

of electricity and furnish channels for transporting logs to the saw-mills. Oats and potatoes are grown, and cattle are bred on the coast-lands of the north. Sheep are grazed in the more sheltered Tamar Valley, and in the drier east.

Tasmania is famous for its apples, its crops accounting for more than half the Commonwealth's total export of this fruit. Many of the orchards lie round *Hobart*, the capital, in the Derwent Valley, which, in addition to exporting apples, preserves and cans quantities of other cool temperate fruits. From Hobart a line runs northward through the centre of the island to *Launceston*, on the Tamar estuary, the chief port in the north.

FIG. 298. Tasmania.

In the Western Highlands the mines of Mount Bischoff yield tin, those of Mount Zeehan copper, and Mount Lyell is the most famous copper-mining centre in Australia. Risdon, near Hobart, utilizes cheap hydro-electric power, with zinc from Broken Hill, in its electrolytic-zinc works.

EXERCISES

1. (a) On a sketch-map of Australia indicate the chief wheat-growing areas. (b) Under the following headings, write an account of wheat production in Australia: Climatic conditions; Areas of production as shown on your sketch-map; Months when crop is (i) sown, and (ii) harvested; Three ports of export; Approximate date of arrival in England.

2. Draw a sketch-map of Australia showing the principal belts of Natural Vegetation. Write brief descriptions of *two* of them.

3. How do you account for the fact that Australia is the most important sheep-rearing country in the world? On a sketch-map of Australia show the chief sheep-rearing districts.

4. (a) Discuss the importance of the Murray and its tributaries as regards: (i) Navigation and (ii) Irrigation. (b) Name *three* important products (excluding minerals) obtained from the basin. Describe briefly the route by which *one* of these products is conveyed to the port of export. Illustrate your answer by a sketch-map.

5. (a) What do you mean by an artesian well? (b) Explain the importance of artesian wells in Australia, paying special attention to the Great Artesian Basin.

6. Describe some of the ways in which the Australian Government and people are attempting to solve one of their great problems of colonization—the question of 'A White Australia'.

7. From what areas in Australia are gold, silver, zinc, copper, tin, iron ore, and coal chiefly obtained? Give your answer in tabular form, and illustrate it by a sketch-map.

8. On a sketch-map of Australia (a) draw a line to enclose the area with less than 10 inches annual rainfall; (b) show by suitable shading (i) the most densely peopled areas; (ii) those with a moderate population; and (iii) those with few or no inhabitants. Account for the differences. (c) What proportion of the people of Australia live in the five great ports?

9. Give an account of the railway system of Australia and show how the position and direction of the chief routes are related to (a) relief, (b) the products of the interior, and (c) the location of the ports.

10. Name *four* important food products which Australia contributes to the needs of Great Britain. In each case name *one* area of production and describe the conditions favouring the product in this area.

11. Under the headings: (i) position, (ii) relief and climate, (iii) products, write an account of Tasmania.

12. Draw fully labelled sketch-maps to show the importance of Sydney, Melbourne, and Brisbane.

13. Fig. 299 shows the chief imports and exports of Australia. What can we learn from them about the geography of the country?

CHAPTER XXXIII

NEW ZEALAND

THE Dominion of New Zealand lies 1,200 miles east of Australia. It consists of the North and the South Islands separated by Cook Strait, the smaller Stewart Island, and a number of lesser islands in the South Pacific. The total area is slightly less than that of the British Isles, but the population is only 2,300,000. With the exception of some 118,000 Maoris, the people are almost entirely of British descent. The main islands extend from latitude 34° S. to latitude 47° S., a distance of approximately 900 miles.

Both the North and the South Islands are mountainous. The Southern Alps—young fold mountains—which form the backbone of the South Island, rise close to the west coast, but on the east are bordered by plains. The snow-clad summits of many peaks rise to over 10,000 feet, and Mount Cook (Aorangi) reaches 12,349 feet. The magnificent glaciers lying above the snow-line, which in the south-west descends to within 700 feet of the sea-level; the U-shaped valleys; the deep, steep-walled fiords of the south-west; and the long, narrow mountain lakes on the borders of the Otago Plateau (a much denuded area of ancient rocks), all remind us that the whole of this region was once heavily glaciated.

• In the North Island other fold mountains, considerably lower than the Southern Alps, rise close to the east coast. In the centre of the island is a volcanic district with cones, hot springs, and geysers. The active volcanoes of Tongariro (6,458 feet), and Ruapehu (9,175 feet) lie south of Lake Taupo, which is drained northward by the Waikato, one of a number of rivers harnessed for hydro-electric power. In the south-west of the North Island rises the extinct volcanic cone of Mount Egmont.

Climate. New Zealand lies in approximately the same latitudes as Italy, but its climate, though of a modified Mediterranean type in the north, is greatly moderated by its insular position, resembling that of the warmer parts of the British Isles rather than that of the Mediterranean Lands.

The greater part of New Zealand lies in the belt of Westerly Winds,

which bring adequate rainfall to the whole country. In the North Island, owing to the absence of a high and continuous mountain

FIG. 300. New Zealand: Structure and Relief.

belt, rainfall is fairly evenly distributed, and even in the 'Mediterranean' north of the island there is no dry season, though the summer months are driest. In the South Island the rainfall on the windward

side of the Southern Alps is heavy, in many districts exceeding 100 inches per annum. The east, lying in the rain shadow of the mountains, is drier, receiving on an average somewhat less than 30 inches.

Natural Vegetation, Crops, and Animals. At one time all the regions with heavy rain were thickly timbered, but so much land has been cleared for pasture that now only 18 per cent. of New Zealand is forested. To-day the most extensive forest areas are the western

FIG. 301. New Zealand: Temperature in Summer (January) and Winter (July); and Mean Annual Rainfall.

slopes of the Southern Alps and the more mountainous parts of the North Island. Native trees, all evergreen, include southern beeches and pines, tree-ferns, and the Kauri pines of the Auckland Peninsula. Of about 20 million acres under cultivation about 18 million consist of sown grasses, and there are also 14 million acres of tussock and other native grasses available for grazing sheep.

There are no native wild animals. Sparrows, deer, and rabbits introduced by early settlers, have proved a pest to farmers, but recently rabbits have been almost wiped out.

The introduction of refrigeration brought prosperity to the New Zealand farmer, for it opened up distant markets for frozen meat and dairy produce. To-day farming is highly mechanized. Improved strains of grasses are sown, and fertilizers are used for top-dressing pastures, a process often carried out by aircraft, also used for sowing and spraying crops, and poisoning rabbits. As a result of such modern methods, yield per acre has risen, and output per farm worker is high.

The mild and moist climate make New Zealand an ideal

FIG. 302. New Zealand: General and Economic.

pastoral country, and farming is mainly concerned with raising sheep and lambs and with dairying. New Zealand is one of the world's chief exporters of dairy produce and frozen meat, and ranks immediately after Australia as an exporter of wool. The Government buys dairy and other primary produce destined for export, paying farmers fixed prices for it.

About 80 per cent. of New Zealand's cattle are raised in the North Island, where much *dairying* is carried on in lowland areas, such as Taranaki. Farms are small. As in Denmark, milk is sent to co-operative factories to be made into butter and cheese. On most dairy farms many lambs are fattened, and pigs are raised to provide hams and bacon for the home and export markets.

Out of nearly 46 million *sheep* rather more than 60 per cent. are reared in the North Island, notably in the drier east and the south, e.g. in the Hawke's Bay district. In the South Island few sheep are found in the west, owing to the heavy rainfall, but many are grazed on the Canterbury Plains and on the eastern slopes of the Southern Alps. As in Australia, shearing is done by bands of men who travel from one station to another. In the North Island much shearing is done by Maoris.

Mixed farming is important on the Canterbury Plains. On a typical farm in this area (about 400 acres) half is usually under grass or green fodder crops to provide pasture for ewes and lambs, and the rest is devoted to cereals and root crops. The paddocks are bounded by gorse hedges or wire fences, and lines of pine trees (*pinus insignis*) which have been planted as wind-breaks.

Natural Regions of the North Island. (1) *The Auckland Peninsula* and the lowlands to the south. Owing to subsidence, the coast of the long, narrow Auckland Peninsula is broken by a number of inlets of the *ria* type, most of which are, however, too shallow to be of much use as harbours. The peninsula is the home of the kauri pine but few stands remain. Much of New Zealand's timber comes from pine forests planted about thirty years ago in the area north and north-east of the Volcanic District, where the port of Maunganui processes wood-pulp and paper for export. Dairying is carried on, notably on the Hauraki Plain, and in the valley of the Waikato on which there are a number of power stations. The mild and sunny climate favours vines and other warm temperate

fruits. *Auckland* (466,000), New Zealand's biggest city, has a harbour on both sides of the island, but as that on the west is shallow the eastern one is used by ships sailing to the Panama Canal and American ports; and to Sydney, a $3\frac{1}{2}$ days' voyage across the Tasman Sea.

(2) *The Volcanic District* lies around Lake Taupo, the largest sheet of water in New Zealand. Most of the Maoris live in this region, and many tourists visit it to see the geysers, hot springs, and the volcanic cones of Ngauruhoe, Tongariro, and Ruapehu.

(3) *The Mountainous South-east* is mainly a sheep-grazing area.

FOREIGN TRADE OF NEW ZEALAND			
EXPORTS		IMPORTS	
WOOL		MACHINERY	
FROZEN MEAT		MOTOR VEH	
BUTTER		TEXTILES	
CHEESE		PETROLEUM	

FIG. 303.

Napier and *Hastings* are the chief towns. The region is subject to occasional earthquakes.

(4) *The Pastoral Plains and Uplands of the South-west* include the Taranaki district and the fertile Wellington Plains. The damp climate is ideal for cattle rearing, and the whole region, especially the Taranaki area, is noted for dairying. *Palmerston North* is the chief town in the north-west. *Wellington* (228,000), on a magnificent hill-girt harbour, was chosen to be the capital of New Zealand on account of its central position.

Natural Regions of the South Island. (1) *The Southern Alps* are a region of unexcelled beauty; while in the south-west corner the steep-sided fiords, called sounds, rival in charm those of Norway or British Columbia. The rivers are useless for navigation, but their waters provide potential and developed hydro-electric power which is widely used in factory and farm. The chief occupations of the isolated strip along the west coast are mining and lumbering. *Westport* and *Greymouth* both export coal mined in the vicinity, and *Hokitika*, south of Greymouth, is a centre for lumbering. From Greymouth a railway to Christchurch climbs the forested uplands to Arthur's Pass, passing under the summit through the Otira Tunnel, one of the longest in the British Commonwealth.

47. NEW ZEALAND—A DAIRY FARM AND A POWER STATION

(Above) A dairy farm. Note the typical box-hedges, the wooden farmhouse, the cowbales and water storage tank (left), and the poles carrying electric cables. Cattle are moved from one paddock to another to avoid overgrazing. (Below) Roxburgh hydro-electric power station, on the Clutha, the chief of a number of hydro-electric power stations in New Zealand.

48. PACIFIC ISLANDS

(Above) A 'High' volcanic island surrounded by a coral reef. ((Below) An Indian home in the Fiji Islands, where rather less than half the population consists of Fijians, and the rest of Indians whose ancestors migrated from India. Photograph by Jasper Stembridge

(2) *The East Coast Region* may be divided into the Canterbury Plain and the Otago Plateau. The former region has been built up of morainic material deposited by rivers after the melting of the ice-sheet that once covered the Southern Alps. Wheat, oats, potatoes, and fodder crops are grown, but sheep farming is the main occupation. *Christchurch* (205,000), the chief town in the South Island, is connected by rail with the port of *Lyttelton* lying to the north of Banks Peninsula. From Christchurch a line runs southward to *Dunedin* (100,000), standing on hills at the head of Otago Harbour, and makes for *Invercargill* (37,000), the principal town of Southland. At one time Southland was the chief area in New Zealand for growing oats, but now it is better known for dairying and for raising fat lambs for export.

(3) *The Tasman Bay-Marlborough Region*. This small area, lying around Tasman Bay and along the east coast of the Marlborough province, is noted for its apples and its cereals. The former are grown round *Nelson*.

EXERCISES

1. (a) Draw a sketch-map of New Zealand and on it show, by suitable shadings, the chief cattle and sheep-farming areas. (b) How do you account for the fact that more than 60 per cent. of the sheep and 80 per cent. of the cattle are bred in the North Island, but that the greater part of the wheat is grown in the South Island?

2. Fig. 303 shows the comparative value of the chief exports and imports of New Zealand. What can we learn from the above about the geography of the country?

3. On a sketch-map of New Zealand (a) Shade the land over 1,500 feet. (b) Name the Southern Alps. (c) Name the Hot Spring District and mark and name a large lake in this area together with the river draining it. (d) Show by arrows the direction of the prevailing winds. (e) Indicate the chief coal-fields. (f) Mark and name the four largest towns. (g) How do you account for the fact that all of these towns are ports?

4. Draw a fully labelled sketch-map to show why Wellington is important. Why do you think this town was chosen to be the capital of New Zealand?

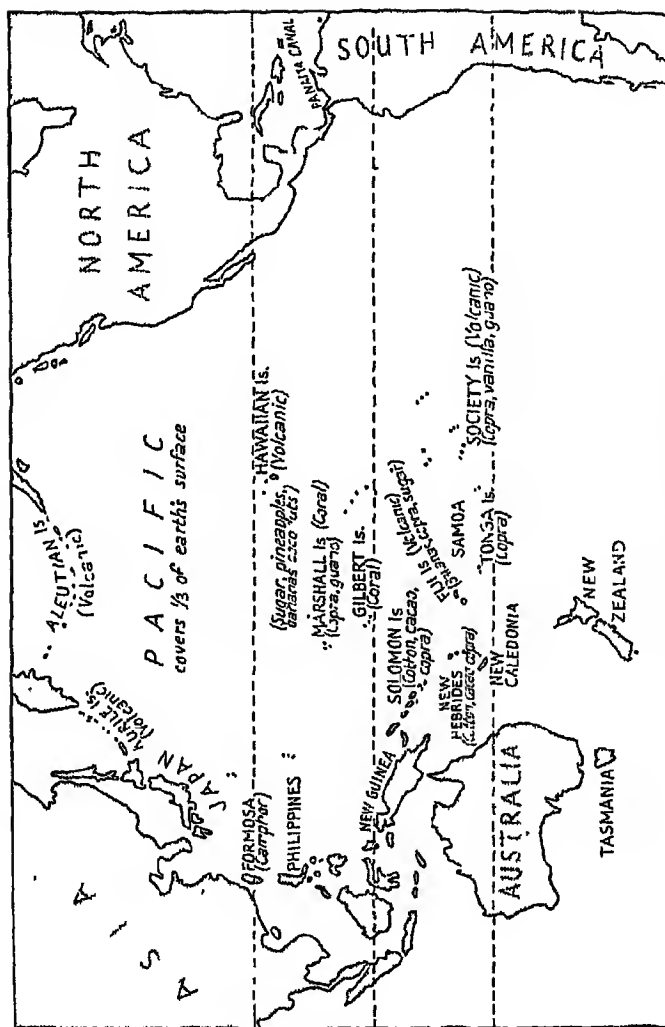

FIG. 304. The Pacific Ocean.

CHAPTER XXXIV

THE PACIFIC ISLANDS

THE PACIFIC

THE Pacific Ocean covers one-third of the earth's surface and contains some of the greatest known depths. Its islands (excluding those off the coast of Asia) are found mainly in the south. They may be divided into (1) *Continental Islands*, such as New Guinea, New Caledonia, and the Bismarck Archipelago, situated on the continental shelf of Australia; and (2) *Oceanic Islands* (Fig. 304).

CONTINENTAL ISLANDS

New Guinea, stretching from the equator to 10° S., is, with the exception of Australia, the largest island in the world. It is separated from the latter by Torres Strait and the Arafura Sea. The island is crossed from east to west by ranges which occupy the centre and north. Owing to the low latitude temperatures are uniformly high, except in the highlands and rain falls throughout the year. The north of New Guinea receives, however, most rain during the southern summer, when the north-west monsoon winds are blowing from Asia towards Australia. In the south the rainfall is heaviest in the southern winter, when the south-east winds are blowing towards South-east Asia.

Dense impenetrable forests spread from the lowlands almost to the crests of the mountains; while along the coasts are many coco-nut plantations yielding copra, and allied products, and banana trees which, with yams, taro, sago, and fish, form the staple foods of the natives. These are mainly of Papuan origin, but there is much race intermixture among the coastal peoples, who are seamen and fishermen. In the little-known interior live primitive tribes, including pygmies, many of whom are still in the Stone Age. Minerals, including copper and gold, are abundant, but so difficult are com-

FIG. 305. New Guinea.

munications that only gold is worked. The mines are in the Bulolo river area: acroplanes are used to convey gold to the port of Salamaua, 25 miles distant, and to transport dredges and other mining machinery, as well as passengers and foodstuffs. In the extreme west of New Guinea, an oil-field at Klamono, with a short pipe-line to the coast at Sorong, began production in 1951. It is the first industrial development in this area.

The west of New Guinea, *West Irian*, formerly Dutch, is now part of the Republic of Indonesia. The east is divided into *Papua*, capital Port Moresby, and the *Territory of New Guinea*. Both areas are administered by Australia under a Trusteeship of the United Nations. Also administered by Australia under this Trusteeship are the *Bismarck Archipelago*, north-east of New Guinea, which includes New Britain and New Ireland and some of the *Solomon Islands*, the remainder being governed by Britain.

New Caledonia, somewhat larger than Wales, is French. It is rich in minerals, notably nickel, iron, and manganese. The chief crops are coffee, coco-nuts, and cotton.

OCEANIC ISLANDS

By far the greater number of the oceanic islands in the Pacific lie in tropical latitudes. As nearly all are in the trade-wind belts their climate is mild and equable: the higher islands receive heavy rain on their windward sides, but some of the low coral islands suffer from drought.

The island folk, numbering somewhat more than a million, may be divided into Micronesians, Melanesians, and Polynesians. The Melanesians, who are found mainly west of longitude 180°, are a black, frizzy-haired people. The Polynesians, whose island homes are chiefly east of longitude 180°, are taller than the Melanesians, and have brown skins and dark hair.

Most of the oceanic islands are either *low* coral islands, like the Marshall and Gilbert Islands, or *high* volcanic islands, such as the Hawaiian, Fiji, and Solomon Islands.

Coral Islands. The *low* islands have been formed by the coral polyp, which builds only in calm, clear, warm, and comparatively shallow salt water. In the open ocean coral islands rise from submarine ridges and peaks whose summits are not far below the surface. As the polyps cannot build above sea-level, newly formed islands are

almost awash. But gradually blocks of coral, broken by the waves, are piled up on the surface, thus increasing the height, until in time the island reached an elevation of 10 to 12 feet, and in the case of old islands of as much as 30 feet above sea-level.

There are three types of coral islands. *Fringing reefs* grow close to and around other islands, which are often of volcanic origin.

FIG. 306. Fringing Reef round High Volcanic Island.

FIG. 307. Coral Atolls.

Barrier Reefs, like the Great Barrier Reef of Australia, lie some distance from the land and usually descend to considerable depths on their seaward side. *Atolls* are belts of coral, often more than a mile wide, circular, oval, and sometimes triangular in shape, which enclose expanses of water called *lagoons*. The lagoons generally, though not always, have an entrance—often deep enough to allow the passage of large ships—on the side opposite the prevailing winds. They vary in size. Some are relatively small, but others are quite large, one in the Marshall Islands actually measuring 100 miles across.

The vegetation on coral islands is usually limited to coco-nut and pandanus (or screw) palms which, springing from the broken coral, meet almost every need of the inhabitants. The chief product is copra. But, truth to tell, romantic though they sound, palm-fringed atolls are uncomfortable homes. Yet since 1935 some of the hitherto isolated and uninhabited atolls that dot the Pacific wastes have attained a new importance as air bases on trans-Pacific routes.

Volcanic Islands. The *high* volcanic islands, which are much larger than the coral islands, rise steeply from the ocean, but their rugged outline is softened by masses of luxuriant vegetation. Their palm-fringed beaches margin a narrow plain, built up by sediment brought down by streams, where such crops as rice, sugar-cane, yams, and pineapples are grown. Among the chief volcanic groups are the Fiji, Samoan, and Hawaiian Islands.

The Fiji Islands (British), lying between latitudes 15° S. and 22° S. on both sides of longitude 180° , consist of about 320 islets and islands, the largest being Viti Levu and Vanua Levu. Thick forests clothe the windward slopes of the islands, where the south-east trades bring a heavy rainfall. There are large sugar-cane plantations in the valleys, and coco-nuts, pineapples, and bananas are also cultivated. The bulk of the population, numbering 345,000, consists of Fijians and Indians. The latter, who are increasing the more rapidly and now slightly outnumber the Fijians, are descendants of labourers who came from India in the eighteen-seventies to work on the sugar plantations. Rain clouds often wreath the wooded mountains behind Suva, the capital, in the south-west of Viti Levu, whose harbour is approached through a gap in a coral reef, which is only distinguished by an irregular line of white foam. Cargo steamers, and liners plying between Sydney, Auckland and Vancouver, call at Suva. From its airport there are services to Sydney (1,800 miles), Auckland (1,150 miles), San Francisco (4,830 miles), and Vancouver (5,200 miles); and also to the Cook Islands, to Tonga, an independent kingdom under British protection, and to Samoa.

Samoa, whose islands are mainly of volcanic origin, is divided into Western Samoa, independent since 1962, and Eastern Samoa, under the jurisdiction of the United States. The capital of Western Samoa is Apia. The harbour of Pago Pago in Eastern Samoa is an American naval base. Copra is the chief export.

The Hawaiian Islands lie in the North Pacific. Their climate resembles that of the Fiji group, for though they lie north of the equator, they are situated in similar latitudes. On the southern lowlands of Hawaii, the largest island, quantities of sugar-cane and pineapples are grown. In the centre of this island the enormous volcano of Mauna Loa rises over 13,000 feet above sea-level, and more than 30,000 feet above the ocean bed. *Honolulu*, the capital and the best-equipped port in the Mid-Pacific, is a focus of trans-

Pacific steamship and air routes. It is a centre for wealthy American tourists attracted by its famous Waikiki beach and by the scenery and climate of the islands. Within easy distance is the great naval and air base of Pearl Harbour. Most of the trade of the Hawaiian Islands is with the United States, sugar and pineapples being the main goods shipped from Honolulu to San Francisco, 5 days journey by sea, but only 11 hours by air. In 1959 the Hawaiian Islands became the 50th State of the United States.

EXERCISES

1. How are coral islands formed? Describe, with examples of each, the chief types of coral islands. Discuss the present and future importance of coral islands in the Pacific.
2. What do you understand by a *high island*? Describe an important *high island* group in the Pacific that forms part of the British Empire and Commonwealth.
3. A roughly circular island, about 300 square miles in area, is situated in the Mid-Pacific: latitude 10° N., longitude 160° E. (approximately). It is of volcanic formation. In the centre of the island is a volcanic cone rising to 7,000 feet. (a) Draw a contour map of the island. Insert contour lines every 1,000 feet. Show by arrows the direction of the prevailing winds. Mark the wetter sides of the island. (b) State what crops you would expect to be grown on the island and in what districts they would probably flourish. Give your reasons.

TEST PAPER: AUSTRALIA, NEW ZEALAND, AND THE PACIFIC ISLANDS

PART I

1. Draw a map of Australia, naming the surrounding oceans, and the ocean currents washing its shores. Show the relation of the currents to the prevailing winds.
2. (a) Describe and compare the *two* most important sea routes from Australian ports to England. (b) How long does it take to travel from Sydney to England (i) by steamer, (ii) by air?
3. Show how modern developments in ocean transport have affected the stock-rearing and fruit-growing industries of Australia and New Zealand? What advantages and disadvantages for trade with Britain has Australia compared with the Argentine?
4. (a) What geographical conditions have contributed towards making Australia the leading sheep-producing country in the world? (b) How do you account for the fact that though New Zealand has only one-third as many cattle as Australia, yet she exports more butter and more cheese?

5. (a) Draw a map of Australia to show the chief belts of natural vegetation. Show how these belts are related to the climatic conditions. (b) Select one belt and describe the occupations of the inhabitants.

PART 2

6. Compare Australia with South Africa, under the headings: relief and structure, climate, natural vegetation, minerals.

7. Select three island groups in the Pacific Ocean. Describe their position, chief products, and their importance to the country owning them.

8. Describe the relief of the South Island of New Zealand, and show how it is related to the rainfall, natural vegetation, and occupations of the people.

9. New Zealand is often called the *Britain of the South*. Discuss this statement and say how far you think it is justified.

10. Write notes on (a) irrigation in Australia; (b) the development of hydro-electric power in New Zealand; and (c) the indigenous animals of Australia.

11. Draw a map of Australia and on it mark and name (a) the Tropic of Capricorn, (b) Bass Strait, (c) the Murray-Darling and the Murrumbidgee, (d) the Great Barrier Reef, (e) a rift valley with two lakes and one gulf that lie within it, (f) the five largest cities, (g) one town where the sun is overhead on 21 December, and (h) the Federal Capital. (i) Shade *one* important irrigated area, (ii) print apples, sugar-cane, pineapples, and bananas each over *one* area noted for their production.

APPENDIX

THE RELATIVE AGE OF ROCKS

<i>Era</i>	<i>Rock Groups</i>	<i>Chief Rocks (with examples from the British Isles)</i>	<i>(1) Land Forms and (2) Life</i>
QUATERNARY.	Recent.	Alluvium (Fenlands), gravels, and sands.	(1) Period of the great Ice Age.
	Pleistocene.		(2) Man and present- day animals appear.
TERTIARY OR CAINOZOIC.	Pliocene.	Sands and gravels (East Anglia).	(1) Great Earth Movements— Alpine Mountain- building.
	Miocene.	Absent from Britain.	
	Oligocene.	Chiefly clays and sands (Hampshire Basin).	
	Eocene.	Sands, gravels, and clays (London Basin).	
SECONDARY OR MESOZOIC.	Cretaceous.	Chalk (Downs), sand- stones, and clays.	(2) Birds and mam- mals appear.
	Jurassic.	Limestones (Portland), sandstones, and shales.	
	Triassic.	New Red Sandstones (Midlands) and marls.	
PRIMARY OR PALAEOZOIC.	Permian.	Red Sandstones, Mag- nesian Limestone.	(1) Armorican Earth Movements at end of Carboniferous times. Caledonian Mountain-building Movements in Siluro-Devonian times. (2) Reptiles and fishes appear. Inverte- brate animals pre- sent in Cambrian Era.
	Carboniferous.	Coal Measures, Mill- stone Grit (Pen- nines), Carboniferous Limestone (Men- dips).	
	Devonian.	Devonian and Old Red Sandstone (Cheviots), shales, slates, and limestones.	
	Silurian.	Sandstones, shales, and limestones.	
	Ordovician.	Sandstones and slates (Central Wales).	
	Cambrian.	Slates and sandstones (North Wales).	
PRE-CAMBRIAN (classification).	(no definite classification).	Sandstones, slates, vol- canic rocks, granites, schists, and gneisses (NW. Scotland).	(1) Several periods of Earth Movements.

Note.—The Mountain-building Movements were associated with much volcanic activity.

The above table is intended for reference only.
